- **CKRE:** sampling edge as rising edge Vs falling edge
- **IFS:** Internal frame sync generation Vs external FS mode
- **FSR:** framed mode Vs unframed mode
- **DIFS:** Data-dependent frame sync Vs data-independent frame sync
- **LFS:** active-high FS Vs active-low FS
- **LAFS:** early frame sync Vs late frame sync
- **PACK:** 16-bit to 32-bit packing enable Vs packing disable
- **GCLKEN:** normal free-running clock Vs Gated clock mode

### Clocking Options

In standard serial mode, the serial ports can either accept an external serial clock or generate it internally. The `SPORT_CTL_A.ICLK` bit determines the selection of these options. For internally-generated serial clocks (`SPORT_CTL_A.ICLK = 1`), the `SPORT_DIV_A.CLKDIV` field configures the serial clock rate from the system clock.

In addition, the serial clock edge can be selected for the sampling or driving serial data and/or frame sync. This selection is performed using the `SPORT_CTL_A.CKRE` bit.

- If `SPORT_CTL_A.CKRE = 0`, incoming data and/or frame sync signals are sampled with respect to falling edge of serial clock; while data and/or frame sync output signals are driven at the rising edge of clock.
- If `SPORT_CTL_A.CKRE = 1`, incoming data and/or frame sync signals are sampled with respect to rising edge of serial clock; while data and/or frame sync output signals are driven at the falling edge of clock.
- The `SPORT_CTL_A.GCLKEN` bit enables clock gating option, in which serial clock is active only during the valid data bits.

## Frame Sync Options

The following sections provide generic information about how frame sync signal is used by the serial port in an operating mode. Note that SPORT halves within a SPORT are independently configurable. Additional information about frame syncs and data sampling that applies to a specific operating mode can be found in [Operating Modes](#).

### Data-Dependent Versus Data-Independent Frame Sync

When a SPORT is configured as a transmitter (`SPORT_CTL_A.SPTRAN = 1`) and if data-independent frame sync select (`SPORT_CTL_A.DIFS`) bit = 0, then an internally-generated transmit frame sync is only output when a new data word has been loaded into the channel transmit buffer of the SPORT. In other words, frame sync signal generation and therefore data transmission is data-dependent. This mode of operation allows data to be transmitted only at specific times.

When SPORT is configured as receiver (`SPORT_CTL_A.SPTRAN = 0`) and if `SPORT_CTL_A.DIFS = 0`, then a receive frame sync signal is generated only when receive data buffer status is not full.

The data-independent frame sync mode allows the continuous generation of the framing signal, regardless of new data in the buffers. Setting `SPORT_CTL_A.DIFS` activates this mode. When `SPORT_CTL_A.DIFS = 1`, a transmit frame sync signal is generated regardless of the transmit data buffer status (if `SPORT_CTL_A.SPTRAN = 1`) or receive data buffer status (if `SPORT_CTL_A.SPTRAN = 0`).

Note that the SPORT DMA controller typically keeps the transmit buffer full. The application is responsible for filling the transmit buffers with data.

### Early Versus Late Frame Syncs

The frame sync signals can be early or late. Frame sync signals can occur during the first bit of each data word (late) or during the serial clock cycle immediately preceding the first bit (early). The `SPORT_CTL_A.LAFS` bit of the serial port control register configures this option.

By default, when `SPORT_CTL_A.LAFS` is cleared (=0), the frame sync signal is configured as early framing signal. This is the normal mode of operation. In this mode, the first bit of the transmit data word is available (and the first bit of the receive data word is latched) in the serial clock cycle after the frame sync is

asserted. The frame sync is not checked again until the entire word has been transmitted (or received). In multichannel operation, this is the case when the frame delay is one.

If data transmission is continuous in early framing mode (in other words, the last bit of each word is immediately followed by the first bit of the next word), then frame sync signal occurs during the last bit of each word. Internally-generated frame syncs are asserted for one clock cycle in early framing mode. This is not an error condition, so the `SPORT_ERR_A.FSERRSTAT` bit is not flagged.

When `SPORT_CTL_A.LAFS` is set ( $=1$ ), late frame syncs are configured; this is the alternate mode of operation. In this mode, the first bit of the transmit data word is available (and the first bit of the receive data word is latched) in the same serial clock cycle that the frame sync is asserted. In multichannel operation, this is the case when frame delay is zero. Receive data bits are latched by serial clock edges, but the frame sync signal is checked only during the first bit of each word. Internally-generated frame syncs remain asserted for the entire length of the data word in late framing mode. Externally-generated frame syncs are only checked during the first bit. They do not need to be asserted after that time period.

Therefore, for early framing, the frame sync precedes data by one cycle; for late framing, the frame sync is checked on the first bit only. The following figure illustrates the two modes of frame signal timing.

**Figure 26-6:** Normal Framing (Early Frame Sync) Versus Alternate Framing (Late Frame Sync)

### Framed Versus Unframed Frame Syncs

The use of frame sync signal is optional in serial port communications. The `SPORT_CTL_A.FSR` (frame sync required) bit determines whether framing signal is required.

When `SPORT_CTL_A.FSR` bit is set ( $=1$ ), a frame sync signal is required for every data word. To allow continuous transmission from the processor, each new data word must be loaded into the transmit buffer before the previous word is shifted out and transmitted.

When `SPORT_CTL_A.FSR` is cleared ( $=0$ ), the corresponding frame sync signal is not required. A single frame sync is required to initiate communications but it is ignored after the first bit is transferred. Data words are then transferred continuously in what is referred to as an unframed mode. Unframed mode is appropriate for continuous reception. The following figure shows the framed vs unframed mode of serial port operation.

**NOTE:** When DMA is enabled in a mode where frame syncs are not required, DMA requests may be held off by chaining or may not be serviced frequently enough to guarantee continuous unframed data flow. Monitor status bits or check for a SPORT Error interrupt to detect underflow or overflow of data.

**Figure 26-7:** Framed Versus Unframed Data Stream

## Logic Level

The framing signals may be active high or active low. The `SPORT_CTL_A.LFS` bit selects the logic level of the frame sync signals.

- When `SPORT_CTL_A.LFS = 0`, the corresponding frame sync signal is active high.
- When `SPORT_CTL_A.LFS = 1`, the corresponding frame sync signal is active low.

Active high is the default polarity of frame sync signal.

## Stereo Modes

The processor serial port support three widely used stereo modes, which are I<sup>2</sup>S mode, Left-Justified mode and right-Justified mode. In these modes, the serial data stream consists of left and right channels. These modes are described in the following sections.

## Channel Order First

The active low frame sync (`SPORT_CTL_A.LFS`) bit, which determines the polarity of frame sync level in DSP serial mode/multichannel mode, holds different meaning for stereo modes of SPORT operation. For left-justified, I<sup>2</sup>S and packed I<sup>2</sup>S modes, the following table demonstrates which word is transmitted or receive first depending on the `SPORT_CTL_A.LFS` bit setting.

**Table 26-13:** Channel Order First Bit Settings

| OPMODE                  | LFS=0 (Left Channel First, Default) | LFS=1 (Right Channel First)   |
|-------------------------|-------------------------------------|-------------------------------|
| Left-Justified          | Data first after rising edge        | Data first after falling edge |
| I <sup>2</sup> S        | Data first after falling edge       | Data first after rising edge  |
| Packed I <sup>2</sup> S | Data first after rising edge        | Data first after falling edge |

## I<sup>2</sup>S Mode

I<sup>2</sup>S mode is a very commonly used stereo mode where in each frame sync cycle two samples of data are transmitted/received—one sample on the low segment of the frame sync, known as left channel; while the other sample on the high segment of the frame sync, known as right channel.

The SPORT can be configured in I<sup>2</sup>S mode by setting `SPORT_CTL_A.OPMODE = 1`, `SPORT_CTL_A.LFS = 0` and `SPORT_MCTL_A.MCE = 0`.

## Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register enable and configure I<sup>2</sup>S mode of operation:

- **SLen:** serial word length select. For I<sup>2</sup>S mode, the range of allowable word length is 5-32 bits.
- **LSBF:** little endian or big endian serial bit format. For I<sup>2</sup>S mode, serial data should be in big endian format (MSB bit is transmitted/received first). But, it can be changed depending on the user's preference when emulating similar non-standard protocol
- **ICLK:** Internal bit clock generation or external bit clock mode
- **IFS:** Internal frame sync generation or external FS mode. In I<sup>2</sup>S mode, master serial port is the one which generates bit clock and L/R clock (frame sync) internally for the serial communication. The serial port which accepts these clocking signals is known as slave. So, in standard I<sup>2</sup>S mode, the `SPORT_CTL_A.IFS` bit should depend (equal to) on `SPORT_CTL_A.ICLK` bit setting. However, as an enhancement, the `SPORT_CTL_A.IFS` bit setting may be changed depending on the application when emulating a non-standard protocol.
- **LFS:** left channel first or right channel first. This bit setting may be changed depending on user's preference to sample right channel first (LFS = 0) or left channel first (LFS = 1).
- **CKRE:** sampling edge as rising edge or falling edge.
- **PACK:** 16-bit to 32-bit packing enable or packing disable.

## Serial Clock and Frame Sync Rates

The serial bit clock rate for internal clocks can be set using a `SPORT_DIV_A.CLKDIV` bit field; while the L/R clock rate for internal frame sync can be set using the `SPORT_DIV_A.FSDIV` bit field in the same register, depending on `SPORT_CTL_A.ICLK` and `SPORT_CTL_A.IFS` bit settings.

The following figure shows the timing in I<sup>2</sup>S mode. Note that in I<sup>2</sup>S mode, the data is delayed by one SCLK cycle and the operation transfer starts on the left channel first.

**Figure 26-8:** Word Select Timing in I2S Mode

Unlike serial port of SHARC processor, the serial port of ADSP-BF60x does not generate a frame sync (L/R clock) edge after the transmission of last word in the DMA (same as behavior in the earlier Blackfin processors). Standard I<sup>2</sup>S receivers look for the edge to latch and read data. Therefore I<sup>2</sup>S slave receivers connected to Blackfin SPORT may not be able to latch the last word of the TX DMA.

## Left-Justified Mode

Left-justified mode is a stereo mode where in each frame sync cycle two samples of data are transmitted/received—one sample on the high segment of the frame sync, known as left channel; while the other sample on the low segment of the frame sync, known as right channel.

This operating mode is simply a subset of the I2S mode. The SPORT can be configured in Left-Justified mode by setting the `SPORT_CTL_A.OPMODE` and `SPORT_CTL_A.LAFS` bits and clearing the `SPORT_MCTL_A.MCE` bit.

## Protocol Configuration Options

Several bits in the `SPORT_CTL_A` control register enable and configure the left-justified mode of operation:

- **SLEN:** serial word length select. For left-justified mode, the range of allowable word length is 5-32 bits.
- **LSBF:** little endian or big endian serial bit format. For left-justified mode, serial data should be in big endian format (MSB bit is transmitted/received first). But, it can be changed depending on the user's preference when emulating similar non-standard protocol
- **ICLK:** Internal bit clock generation or external bit clock mode
- **IFS:** Internal frame sync generation or external FS mode. In left-justified mode, master serial port is the one which generates bit clock and L/R clock (frame sync) internally for the serial communication. The serial port which accepts these clocking signals is known as slave. So, in standard left-justified mode,

the `SPORT_CTL_A.IFS` bit should depend (equal to) on `SPORT_CTL_A.ICLK` bit setting. However, as an enhancement, the `SPORT_CTL_A.IFS` bit setting may be changed depending on the application when emulating a non-standard protocol.

- **LFS:** left channel first or right channel first. In standard left-justified mode, left channel is sampled first (corresponds to `SPORT_CTL_A.LFS = 0`). However, `SPORT_CTL_A.LFS` bit setting may be changed depending on user's preference to sample right channel first (first data after rising edge of L/R clock).
- **CKRE:** sampling edge as rising edge or falling edge.
- **PACK:** 16-bit to 32-bit packing enable or packing disable.

## Serial Clock and Frame Sync Rates

The serial bit clock rate for internal clocks can be set using a `SPORT_DIV_A.CLKDIV` field; while the L/R clock rate for internal frame sync can be set using `SPORT_DIV_A.FSDIV` field, depending on `SPORT_CTL_A.ICLK` and `SPORT_CTL_A.IFS` bit settings. The following figure shows the serial port timing in left-justified mode (it is shown in MSB bit first format, but LSB bit first format is also possible). As shown, the first bit of a word is transmitted/received in the same clock cycle as the word select (`SPORT_FS`) signal changes.

**Figure 26-9:** Word Select Timing in Left-Justified Mode

## Right-Justified Mode

Right-justified mode is a standard commonly available in most of the SPORT compatible devices such as ADC and DACs. Right-justified mode requires that the design align the data to the end of the frame sync. While the SPORTs in earlier Blackfin processors aligned the serial data with the start of the frame sync (used with left-justified or  $I^2S$  mode) the ADSP-BF60x has a `SPORT_CTL_A.RJUST` bit that aligns to the end of the frame sync.

The following figure shows the SPORT timing in right-justified mode. As shown, the transmitter aligns the data to be transmitted such that the last bit of the serial word is sent in the last clock cycle of the word select (frame sync) signal marking the channels. The timing seems similar to left-justified mode (where the transmitter sends the MSB bit of the serial word in the same clock cycle as the word select signal changes), but data is shifted such that it aligns to end of the channel.

**Figure 26-10:** Word Select Timing in Right-Justified Mode

**NOTE:** For some SPORT compatible ADC or DACs (for example the AD1871) right-justified mode is limited to some commonly used ratios such as 64 FS and 128 FS as the bit clock frequency (where FS is the sampling frequency of ADC/DACs, known as L/R clock or the frame sync of the SPORT). The right-justified mode implemented in the ADSP-BF60x SPORT supports up to 128 FS.

As an illustration, consider the SPORT timing for right-justified mode, as shown in the figure below. If the L/R clock runs at the FS rate and the SPORT clock at the 64 FS rate, the frame sync width (either channel) is limited to 32 SPORT clock periods or 32 bits per channel. If the data is confined to 24 bits, the SPORT introduces a  $32 - 24 = 8$  bit clock delay before it starts to transmit/capture data.

**Figure 26-11:** Timing Comparison Between Different Stereo Modes

Similarly, if 128 FS bit clock frequency is to be supported, then the frame sync width becomes 64 serial clock periods (bits) per channel. In this case, the delay can be a maximum of  $(64 - \text{minimum serial data})$

length in right-justified mode) = 59 bits (the minimum `SPORT_CTL_A.SLEN` setting is 4). This implies that a 6-bit counter is needed to set this delay.

Therefore, using this counter in right-justified mode, the starting point of the first bit is delayed so that the serial data is aligned properly with the end of the channel. A 6-bit counter is added for this purpose in the stereo mode. This counter is programmed by writing into the `SPORT_MCTL_A` 16-21 bit field. Note that these bits are used to configure the window offset size in multichannel mode. But since stereo serial mode and multichannel mode are mutually exclusive, the separation of role of this field in each mode is clearly defined and implemented. The software has to configure this register with the appropriate delay keeping in mind the word length (`SPORT_CTL_A.SLEN`) and the number of bit clocks in one channel (left/right).

## Timing Control Bits

The following bits in the `SPORT_CTL_A` register enable and configure right-justified mode.

- **SLEN:** serial word length select. For right-justified mode, the range of allowable word length is 5-32 bits.
- **LSBF:** little endian or big endian serial bit format. For right-justified mode, serial data should be in big endian format (MSB bit transmitted/received first). But, it can be changed depending on the application when using non-standard protocol.
- **ICLK:** Internal bit clock generation or external bit clock mode
- **IFS:** Internal frame sync generation or external FS mode.
- **LFS:** left channel first or right channel first. In standard right-justified mode, the left channel is sampled first (corresponds to `SPORT_CTL_A.LFS = 0`). However, the `SPORT_CTL_A.LFS` bit setting may be changed depending on the application to sample the right channel first (first data after falling edge of L/R clock).
- **CKRE:** sampling edge as rising edge or falling edge.
- **PACK:** 16-bit to 32-bit packing enable or packing disable.
- **MCTL16-21:** 6-bit counter depends on `SPORT_CTL_A.SLEN` and number of bit clocks in a channel.

## Serial Clock and Frame Sync Rates

The serial bit clock rate for internal clocks can be set using the `SPORT_DIV_A.CLKDIV`; while the L/R clock rate for internal frame sync can be set using the `SPORT_DIV_A.FSDIV` bit field in the same register, depending on `SPORT_CTL_A.ICLK` and `SPORT_CTL_A.IFS` bit settings.

## Multichannel Mode

The processor's SPORTs offer a multichannel mode of operation, which allows the SPORT to communicate in a time division multiplexed (TDM) serial system. In multichannel communications, each data word

of the serial bit stream occupies a separate channel. Each word belongs to the next consecutive channel. For example, a 24-word block of data contains one word for each of the 24 channels.

The multichannel mode of SPORT can be selected by setting `SPORT_CTL_A.OPMODE = 0` and `SPORT_MCTL_A.MCE = 1`.

Up to 128 channels are available for transmitting or receiving. The SPORT can automatically select some words for particular channels while ignoring others. In other words, each SPORT can receive or transmit data selectively from any of the 128 channels. These 128 channels can be any 128 out of the 1024 total channels in the system. The SPORT can do any of the following on each channel:

- Transmit data (`SPORT_CTL_A.SPTRAN = 1`)
- Receive data (`SPORT_CTL_A.SPTRAN = 0`)
- Do nothing during inactive channels

Optionally, data companding and DMA transfers can be used in multichannel mode on both primary and secondary data lines.

The SPORT multichannel select registers (`SPORT_CS0_A`) must be programmed before enabling SPORT operation for multichannel mode. This is especially important in DMA data unpacked mode, since the SPORT data buffers begin operation immediately after the SPORT data lines are enabled. The `SPORT_MCTL_A.MCE` must also be enabled prior to enabling SPORT operation.

Multichannel mode operates completely independently and each SPORT uses its own serial clock and frame sync signal either internally generated or externally provided.

## Protocol Configuration Options

The following bits in the `SPORT_CTL_A` and `SPORT_MCTL_A` registers enable and configure multichannel mode.

- SLEN: serial word length select
- LSBF: little endian or big endian serial bit format
- ICLK: Internal clock generation or external clock mode
- CKRE: sampling edge as rising edge or falling edge
- IFS: Internal frame sync generation or external FS mode
- LFS: active-high FS or active-low FS
- PACK: 16-bit to 32-bit packing enable or packing disable
- MFD: Multichannel frame delay
- WSIZE: Number of multichannel channels
- WOFFSET: window offset size

- MCPDE: Multichannel DMA packing enable

## Clocking Options

In multichannel mode, the SPORTs can either accept an external serial clock or generate it internally. The `SPORT_CTL_A.ICLK` bit determines the selection of these options. For internally-generated serial clock (`SPORT_CTL_A.ICLK = 1`), of the `SPORT_DIV_A.CLKDIV` bit field configures the serial clock from the system clock.

In addition, the serial clock edge can be selected for the sampling or driving serial data and/or frame sync. This selection is performed using the `SPORT_CTL_A.CKRE` bit.

- If `SPORT_CTL_A.CKRE = 0`, incoming data and/or frame sync signals are sampled with respect to falling edge of serial clock; while data and/or frame sync output signals are driven at the rising edge of clock.
- If `SPORT_CTL_A.CKRE = 1`, incoming data and/or frame sync signals are sampled with respect to rising edge of serial clock; while data and/or frame sync output signals are driven at the falling edge of clock.

## Frame Sync Options

The frame sync signal synchronizes the channels and restarts each multichannel sequence. The `SPORT_FS` signal initiates the start of the channel 0 data word. The frame sync period in multichannel is defined as:

$$\text{FS period} = [(\text{SPORT\_CTL\_A.SLEN} + 1) \times \text{number of channels}] - 1$$

The frame sync can be configured in master or slave mode based on the setting of the `SPORT_CTL_A.IFS` bit and its logic level can be changed using the `SPORT_CTL_A.LFS` bit.

In multichannel mode, frame sync timing is similar to late frame mode (though the `SPORT_CTL_A.LAFS` bit is reserved in this mode)—the first bit of the transmit data word is available and the first bit of the receive data word is sampled in the same serial clock cycle that the frame sync is asserted, provided that multichannel frame delay (`SPORT_MCTL_A.MFD`) is set to 0.

The frame sync signal is used for the block or frame start reference, after which the word transfers are performed continuously with no further frame sync signals required during the ongoing frame for different channels. Therefore, internally generated frame syncs are always data independent (`SPORT_CTL_A.DIFS` bit is reserved).

## Transmit Data Valid (TDV)

Each serial port has its own Transmit Data Valid signal (`SPORT_ATDV`) which is active during the transmission of enabled words. Because the serial port signals are three-stated when the time slot is not active, the `SPORT_ATDV` signal specifies if the SPORT data is being driven by the processor. It serves as an output-enabled signal for the data transmit pin. After the transmit data buffer is loaded, transmission begins and the `SPORT_TDV` signal is asserted.

The polarity of this Transmit Data Valid signal is always active high in that `SPORT_ATDV` is asserted high when a data is transmitted during the active channel slot of serial port.

The following figure shows an example of timing for a multichannel transfer having following characteristics.

- The half SPORT pair of SPORT0, A and B, is configured as a transmitter and receiver respectively; while half SPORT A of SPORT1 is configured as transmitter.
- The serial clock and frame sync signals are input to all of these HSPORTs.
- Only primary channels of these SPORTs are enabled (0).
- Multichannel is configured to 8 channels.
- SPORT0\_A drives data (on its primary data line) during slot 1–0 which asserts SPORT0\_ATDV for 2 slots.
- SPORT1\_A drives data (on its primary data line) during slot 3–2 which asserts SPORT1\_ATDV for 2 slots.
- SPORT0\_B receives data (from its primary data line) during slot 3–0.

Figure 26-12: Multichannel Timing

Active Channel Selection Registers (SPORT\_CS0\_A)

In multichannel mode, SPORT supports up to 128 channels for transmitting or receiving. It can receive or transmit data selectively from any of the 128 channels. Specific channels can be individually enabled or disabled, using multichannel selection registers (CSx), to select the words that are transmitted or received

during multichannel communications. Data words from the enabled channels are transmitted or received, while disabled channel words are three-stated or ignored.

Each of the four multichannel selection registers is 32 bits in length. Therefore these registers provide channel selection for 128 (0 to 127) channels. Setting a bit enables that channel so that the serial port selects its word from the multiple-word block of data (for either receive or transmit). The 128 channels are sequentially numbered from bit 0 in the CS0 register to bit 31 of SPORT\_CS3\_A register. As an example setting bit 13 of the SPORT\_CS1\_A register enables channel number 45 ( $31+13+1$ ); similarly setting bit 5 of the SPORT\_CS3\_A register enables channel number 101 ( $31+32+32+5+1$ ).

## **Multichannel Frame Delay (MFD)**

The 4-bit multichannel frame delay (SPORT\_MCTL\_A.MFD) field in the multichannel control registers (MCTL\_x) specifies a delay between the frame sync pulse and the first data bit in frame. The value of SPORT\_MCTL\_A.MFD is the number of serial clock cycles of the delay. This multichannel frame delay allows the processor to work with different types of telephony interface devices.

A value of zero for SPORT\_MCTL\_A.MFD causes the frame sync to be concurrent with the first data bit. The maximum value allowed for SPORT\_MCTL\_A.MFD is 15. If SPORT\_MCTL\_A.MFD>0, a new frame sync may occur during the last channels of a previous frame, which is considered as valid frame sync signal. *If more than 15 bits frame delay is required, the Window Offset field may be used to delay the start of channel 0.*

## **Number of Multichannel Slots (WSIZE)**

Select the number of channels used in multichannel operation by using the 7-bit SPORT\_MCTL\_A.WSIZE field in the multichannel control register. Set SPORT\_MCTL\_A.WSIZE to the actual number of channels minus one ( $\text{SPORT\_MCTL\_A.WSIZE} = \text{Number of channels} - 1$ ). So, the granularity of number of channels selected is 1.

A 10-bit field in the multichannel mode status register, SPORT\_MSTAT\_A, holds the channel number which is being serviced in the multichannel operation.

## **Window Offset (WOFFSET)**

The window offset (SPORT\_MCTL\_A.WOFFSET25-16) field of the SPORT\_MCTL\_A register specifies where in the 1024-channel range to place the start of the active window. A value of 0 specifies no offset and 896 ( $1024 - 128$ ) is the largest value that allows using all 128 channels.

As an example, a program could define an active window with 7 multichannel slots ( $\text{SPORT\_MCTL\_A.WSIZE} = 8$ ) and an offset of 93 ( $\text{SPORT\_MCTL\_A.WOFFSET} = 93$ ). This 8-channel window then resides in the range from 93 to 100.

Neither the window offset nor the number of multichannel slots (SPORT\_MCTL\_A.WSIZE) can be changed while the SPORT is enabled. If the combination of the window size and the window offset would place any portion of the window outside of the range of the channel counter, none of the out-of-range channels in the frame are enabled.

## Companding Selection

Like all other operating modes, companding logic can be applied to serial data. In transmit mode, compression logic is applied to the data to be transmitted; while in receive mode, expansion logic can be applied to received data. The two widely used companding algorithms, A-law and  $\mu$ -law can be applied by configuring `SPORT_CTL_A.DTYPE` field of the control register.

If companding is enabled, the companding algorithm is applied to both the data paths. In multichannel mode, companding can be applied to either all or none of the enabled channels, (companding cannot be selected on a per-channel basis).

## Multichannel DMA Data Packing (MCPDE)

Multichannel DMA data packing and unpacking are specified with the `SPORT_MCTL_A.MCPDE` bit setting.

If the bits are set, indicating that data is packed, the SPORT expects the data contained by the DMA buffer corresponds only to the enabled SPORT channels. For example, if an MCM frame contains 10 enabled channels, the SPORT expects the DMA buffer to contain 10 consecutive words for each frame.

If the bits are cleared (the default, indicating that data is not packed), the SPORT expects the DMA buffer to have a word for each of the channels in the active window, whether enabled or not, so the DMA buffer size must be equal to the size of the window. For example, if only channel number 1 and 10 are enabled, then DMA buffer size would have to be 10 words (unless the secondary side is enabled). The data to be transmitted or received would be placed at addresses 1 and 10 of the buffer, and the rest of the words in the DMA buffer would be ignored.

## Multichannel Frame

A multichannel frame contains more than one channel, as specified by the `SPORT_MCTL_A.WSIZE` field and window offset field of multichannel control register. A complete multichannel frame consists of 1–1024 channels, starting with channel 0. The particular channels of the multichannel frame that are selected for the SPORT are a combination of the window offset, the window size, and the multichannel select registers.

The following figure illustrates the relationship between different parameters of multichannel timings. Frame length is set by frame sync divider or external frame sync period

**Figure 26-13:** Relationships for Multichannel Parameter

## Packed I<sup>2</sup>S Mode

A packed I<sup>2</sup>S mode is available in the SPORT and used for audio codec communications using multiples channels. This mode allows applications to send more than the standard 32 bits per channel available through standard I<sup>2</sup>S mode. Packed mode is implemented using standard multichannel mode (and is therefore programmed similarly to multichannel mode).

The SPORT can be configured in packed I<sup>2</sup>S mode by setting the `SPORT_CTL_A.OPMODE` bit and the `SPORT_MCTL_A.MCE` bit.

Similar to multichannel mode, packed I<sup>2</sup>S mode also supports the maximum of 128 channels as the maximum of (128 x 32) bits per left or right channel.

As shown in the following figure, packed waveforms are the same as the wave forms used in multichannel mode, except that the frame sync is toggled for every frame, and therefore emulates I<sup>2</sup>S mode. So it is a hybrid between multichannel and I<sup>2</sup>S mode.

**Figure 26-14:** Packed I<sup>2</sup>S Mode 128 Operation

## Protocol Configuration Options

Several bits in the SPORT\_CTL\_A and SPORT\_MCTL\_A registers enable and configure packed I<sup>2</sup>S mode.

- SLEN: serial word length select
- LSBF: little endian or big endian serial bit format
- ICLK: Internal clock generation or external clock mode
- CKRE: sampling edge as rising edge or falling edge
- IFS: Internal frame sync generation or external FS mode
- LFS: left-channel first or right channel first
- PACK: 16-bit to 32-bit packing enable or packing disable
- MFD: Multichannel frame delay
- WSIZE: Number of multichannel channels
- WOFFSET: window offset size
- MCPDE: Multichannel DMA packing enable

## Clocking Options

In packed mode, the serial ports can either accept an external serial clock or generate it internally. The SPORT\_CTL\_A.ICLK register determines the selection of these options. For internally-generated serial

clock (`SPORT_CTL_A.ICLK = 1`), the `SPORT_DIV_A.CLKDIV` bit field configures the serial clock rate from the system clock.

The programs can also select the serial clock edge that is used for sampling or driving serial data and/or frame syncs. This selection is performed using the `SPORT_CTL_A.CKRE` bit.

## Frame Sync Options

The frame sync period in packed mode is defined as:

$$\text{FS period} = [\text{SPORT\_CTL\_A.SLEN} + 1] \times \text{number of channels} - 1.$$

The frame sync can be configured in master or slave mode depending on the `SPORT_CTL_A.IFS` bit setting of serial port control register. Moreover the logic level can be changed with the `SPORT_CTL_A.LFS` bit setting.

## Gated Clock Mode

Some of the ADC/DACs support the SPI compatible protocol for the interface. To communicate with such ADC/DACs, the serial port must support the gated clock mode of operation, in which the data valid information is embedded into the clock. Therefore, in gated clock mode of, the clock should be active only when active data is being transmitted or received.

The processor features the gated clock function. The `SPORT_CTL_A.GCLKEN` (Gated clock mode select) control bit, is used to configure the serial port in gated clock mode. To enable gated clock mode of operation, SPORT must be programmed to comply with the following requirements.

- Gated clock mode feature is available in standard serial mode, left-justified and I<sup>2</sup>S mode of operation only.

[Note that among the stereo modes, right justified mode cannot be operated in gated clock mode because during the inactive period in a frame (the period between the leading edge of the frame sync and the first active data bit), there is a delay counter running inside the serial port. The counter operates on the serial clock and any interruption in clock makes the counter go out of sync].

- Gated clock mode has the following valid settings for other control bits.
  - Both serial clock and frame sync signals generated internally
  - Both serial clock and frame sync signals provided externally
  - Frame sync not required' mode (`SPORT_CTL_A.FSR = 0`) not supported
  - `SPORT_CTL_A.DIFS` should be programmed as 0 in transmit mode; while it should be programmed as 1 in receive mode.
- There are few necessary conditions to be satisfied when gated clock mode is enabled-

- Need at least 7 serial clock cycles between enabling the SPORT and first frame sync. If this requirement is not met, the SPORT may drop the first data. (For subsequent data this requirement is not applicable).
- Frame sync should be in the inactive (deasserted) state when the SPORT is enabled. Else, one extra cycle (in addition to the above mentioned) is needed before the frame sync can be applied. If this requirement is not met, the SPORT may drop the first data.
- For edge detected frame sync, the frame sync should transition back to inactive state before the current word transmission/reception is complete (or when the clock is still running). If this requirement is not met, the SPORT does not recognize the next valid frame sync and skips the channel. The SPORT continues to skip the frame syncs until the frame sync transitions back to an inactive state when the clock is active.

## Data Transfers

Serial port data can be transferred to/from internal or external memory in two different methods:

- Core-driven single word transfers
- DMA-driven multiple words transfers, with multiple work units.

DMA transfers can be set up to transfer a configurable number of serial words between the serial port transmit or receive data buffers and internal memory automatically. Core-driven transfers use SPORT interrupts to signal the processor core to perform single word transfers to/from the serial port data buffers.

The following sections provide information on core-driven and DMA-driven data transfers.

## Data Buffers

When programming the serial port data channels (primary and/or secondary) as a transmitter by setting `SPORT_CTL_A.SPTRAN = 1`, only the corresponding transmit data buffers (`SPORT_TXPRI_A` and `SPORT_TXSEC_A`) become active while the receive data buffers (`SPORT_RXPRI_A` and `SPORT_RXSEC_A`) remain inactive. Similarly, when the SPORT data channels are programmed for receive operation (`SPORT_CTL_A.SPTRAN = 0`), then only corresponding receive data buffers (`SPORT_RXPRI_A` and `SPORT_RXSEC_A`) are activated. Do not attempt to read or write inactive data buffers. If the processor operates on the inactive transmit or receive buffers while the SPORT is enabled, unpredictable results may occur.

Each of these buffers is 32-bit wide (corresponds to maximum serial data word length). When using word lengths less than 32-bits for SPORT operation, the data in these buffers is automatically right-justified (the LSB bit of data at the bit 0 location of the buffer). The upper unused bits may be zero-filled or sign-extended depending on `SPORT_CTL_A.DTYPE` field.

## **Transmit Data Buffers (SPORT\_TXPRI\_A and SPORT\_TXSEC\_A)**

When enabled as a transmitter (SPORT\_CTL\_A.SPTRAN = 1), each SPORT half has its own set of transmit data buffers. The primary (0) and secondary (1) data paths of each SPORT half have separate data buffers, referred to as SPORT\_TXPRI\_A and SPORT\_TXSEC\_A respectively.

These transmit data buffers are the 32 bits wide. These buffers must be loaded with the data to be transmitted on the primary and secondary data channels. The data is loaded automatically by the DMA controller or loaded manually by the program running on the processor core.

Together with the output shift register, transmit data buffers act like a two-location FIFO. If data packing is disabled (SPORT\_CTL\_A.PACK = 0), the transmit path can hold as many as three data words. If data packing is enabled (SPORT\_CTL\_A.PACK = 1), it can hold two packed data words at any given time.

When the transmit shift register becomes empty (transfer out all the bits of previous word), data in the transmit data buffer is automatically loaded into it. An interrupt occurs when the output transmit shift register has been loaded, signifying that the transmit data buffer is empty and ready to accept the next word. This interrupt does not occur when serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary data path of a SPORT half is enabled, programs should not write to the inactive secondary transmit data buffer and vice-a-versa. If the core keeps writing to the inactive buffer, the status of that transmit buffer becomes full and this may cause the core to hang indefinitely since data is never transmitted to the output shift register.

## **Receive Data Buffers (SPORT\_RXPRI\_A and SPORT\_RXSEC\_A)**

When enabled as receiver (SPORT\_CTL\_A.SPTRAN = 0), each SPORT half has its own set of receive data buffers. The primary (0) and secondary (1) data paths of each SPORT half have separate data buffers, referred as SPORT\_RXPRI\_A and SPORT\_RXSEC\_A respectively. Together with input shift register, the receive data buffers act like a three-location FIFO, as the receive path has two data registers.

These receive data buffers are the 32 bits wide. These buffers are automatically loaded from the receive shift register when a complete word has been received into it. An interrupt occurs when the receive data buffer is loaded, signifying that new data is available in the receive data buffer and is ready to read. This interrupt does not occur when the serial port is operating in DMA mode or when the corresponding interrupt enable mask bit is set.

If only the primary data path of a SPORT half is enabled, programs should not read from the inactive secondary receive data buffer and vice-a-versa. If the core keeps reading from the inactive buffer, the status of that receive buffer becomes empty and this may cause the core to hang indefinitely since new data is never received via the input shift register.

## **Data Buffer Status**

Serial ports provide status information about data buffers via the SPORT\_CTL\_A.DXSPRI (primary channel data buffer status) and SPORT\_CTL\_A.DXSSEC (secondary channel data buffer status) bits and error status

via `SPORT_CTL_A.DERRPRI` (primary channel error status) and `SPORT_CTL_A.DERRSEC` (secondary channel error status) bits. Depending on the `SPORT_CTL_A.SPTRAN` bit setting, these bits reflect the status of either `SPORT_TXPRI_A` and `SPORT_TXSEC_A` transmit data buffers or `SPORT_RXPRI_A` and `SPORT_RXSEC_A` receive data buffers. These bits indicate whether the buffers are full, partially full or empty.

When attempting to read from an empty receive buffer or to write to a full transmit buffer, the access is delayed until the buffer is ready. This delay is called a core processor hang. To avoid these conditions, always check the buffer status to determine if the access can be made. The status bits in the `SPORT_CTL_A` register are updated during reads and writes from the core processor even when the serial port is disabled.

Two complete 32-bit words can be stored in the receive buffer while a third word is being shifted in. Therefore, almost three complete words can be received without the receive buffer being read before an overflow occurs. After receiving the third word completely, a shift register contents overwrite the second word if the first word has not been read out (by the processor core or the DMA controller). When this happens, the receive overflow status is flagged through the error status bits of the `SPORT_CTL_A` register. The overflow status is generated on the last bit of the third word. The `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DXSSEC` status bits are sticky read-only bits and are cleared by disabling the serial port.

**NOTE:** The status bits in the `SPORT_CTL_A` register are updated during reads and writes from the core processor even when the serial port is disabled.

## Data Buffer Packing

When the SPORT is configured as a receiver with a serial data word length of 16 or less, then received data words may be packed into a 32-bit word. Similarly, if the SPORT is configured as transmitter with a serial data word length of 16 or less, then 32-bit words being transmitted may be unpacked into 16-bit words. This packing/unpacking feature is selected by the `SPORT_CTL_A.PACK` bit.

When `SPORT_CTL_A.PACK = 1`, two successive words received are packed into a single 32-bit word, or each 32-bit word is unpacked and transmitted as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15–0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31–16. This applies to both receive (packing) and transmit (unpacking) operations. In this case, the transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word.

Companding can be used with word packing or unpacking.

**NOTE:** When 16-bit received data is packed into 32-bit words and stored in normal word space in processor internal memory, the 16-bit words can be read or written with short word space addresses.

## Single Word (Core) Transfers

Individual data words may also be transmitted or received by the serial ports, with interrupts occurring as each data word is transmitted or received. When a serial port is enabled and corresponding DMA is disabled, the SPORT interrupts are generated whenever a complete word has been received in the receive data buffer, or whenever the transmit data buffer is not full.

When performing core driven transfers, write to the buffer designated by the `SPORT_CTL_A.SPTRAN` bit setting. For DMA driven transfers, the SPORT logic performs the data transfer from internal memory to/from the appropriate buffer depending on the `SPORT_CTL_A.SPTRAN` bit setting. If the inactive SPORT data buffers are read or written to by the core while the SPORT is being enabled, the core may hang. For example, if a SPORT is programmed to be a transmitter, while at the same time the core reads from the receive buffer of the same SPORT, the core may hang just as it would if it were reading an empty buffer that is currently active and waits for the status to change. This may lock up the core until the SPORT is reset.

To avoid hanging the processor core, check the status of appropriate data buffers when the processor core tries to read a word from a serial port's receive buffer or writes a word to its transmit buffer. The full/empty status can be read using the `SPORT_CTL_A.DXSPRI` and `SPORT_CTL_A.DXSSEC` bits.

## DMA Transfers

Direct memory access (DMA) provides a mechanism for receiving or transmitting an entire block of serial data before an interrupt is generated. When SPORT DMA is not enabled, the SPORT generates an interrupt every time it receives or starts to transmit a data word. The processor's on-chip DMA controller handles the DMA transfer, allowing the processor core to continue running until the entire block of data is transmitted or received. Service routines can then operate on the block of data rather than on single words, significantly reducing overhead.

Therefore, set the direction bit, DMA enable bit and the serial port enable bit before initiating any operations on the SPORT data buffers. Do not try to access data buffers when the associated DMA channel of serial port is enabled. If the processor operates on the inactive transmit or receive buffers while the SPORT is enabled, it can cause unpredictable results.

Each SPORT half has a dedicated DMA channel, which serves both primary and secondary data paths. In transmit mode, the DMA channel alternatively writes to the primary transmit data buffer and the secondary transmit data buffer. Software must interleave the data of primary and secondary channels into the DMA's transmit buffer. Similarly, in receive mode, the DMA channel alternatively reads from the primary receive data buffer and the secondary data buffer and software must de-interleave the data corresponding to the primary and secondary channels from the DMA's receive buffer.

If the SPORT is configured in stereo mode, the same DMA channel drives/receives both the left and right channels of the enabled data paths (primary and/or secondary). Therefore, in transmit mode, software must interleave the left and right channels' data (of the enabled data paths) into the DMA's transmit buffer. Similarly in receive mode, software should de-interleave the left and right channel data (of the enabled paths) from the DMA's receive buffer.

Since both primary and secondary data paths share the single DMA channel, each SPORT half share a common interrupt vector. Optionally the DMA controller can generate an interrupt at the end of the completion of a DMA transfer and at the end of each work unit of DMA.

The SPORT DMA channels are assigned a higher priority than all other DMA channels (for example, the SPI port) because of their relatively low service rate and their inability to hold off incoming data. Having

higher priority causes the SPORT DMA transfers to be performed first when multiple DMA requests occur in the same cycle. The serial port DMA channels are numbered and prioritized as shown in the following table.

**Table 26-14:** SPORT DMA Channel Assignments

| SPORT Channels |              | DMA Channel Number |
|----------------|--------------|--------------------|
| SPORT0         | SPORT half-A | 0                  |
|                | SPORT half-B | 1                  |
| SPORT1         | SPORT half-A | 2                  |
|                | SPORT half-B | 3                  |
| SPORT2         | SPORT half-A | 4                  |
|                | SPORT half-B | 5                  |

Although the DMA transfers are performed with 32-bit words, the SPORTs can handle word sizes from 4 to 32 bits (as defined by `SPORT_CTL_A.SLEN` field). If serial data length is 16 bits or smaller, two data can be packed into 32-bit words for each DMA transfer. This option is selected by setting the `SPORT_CTL_A.PACK` bit. When serial port data packing is enabled (`SPORT_CTL_A.PACK = 1`), the transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word. For more information, see [Data Buffer Status](#).

**NOTE:** The DMA channel of a SPORT can access both internal memory and external memory of the processor without any core overhead.

## Error Detection

When the serial port is configured as a transmitter, the `SPORT_CTL_A.DERRPRI` (primary channel error status) and `SPORT_CTL_A.DERRSEC` (secondary channel error status) bits provide transmit data buffer underflow status for the primary and secondary data paths respectively (it indicates that frame sync signal occurred when the transmit data buffer was empty). The serial port transmits data whenever it detects a framing signal.

- 0 = No frame sync signal occurred when TX data buffer is empty (no underflow).
- 1 = Framing signal occurred when TX buffer was empty (underflow).

Similarly if SPORT configured as a receiver, these `SPORT_CTL_A.DERRPRI` and `SPORT_CTL_A.DERRSEC` bits provide receive overflow status of primary and secondary receive data buffers. In other words it indi-

cates that a channel has received new data when the receive buffer is full so new data overwrites existing data. The serial port receives data whenever it detects a framing signal.

- 0 = No frame sync signal occurred when RX data buffer is full (no overflow).
- 1 = Frame sync signal occurred when RX data buffer was full (overflow).

Besides these status flagging for underflow and overflow errors, each SPORT half contains an error register (SPORT\_ERR\_A) and a dedicated interrupt channel, known as status interrupt. This interrupt can be optionally triggered based on the error status of primary and secondary data lines as reflected in SPORT\_ERR\_A.DERRPSTAT and SPORT\_ERR\_A.DERRSSTAT bits respectively. The SPORT\_ERR\_A.DERRPMSK (primary channel data error interrupt enable) and SPORT\_ERR\_A.DERRSMSK (secondary channel data error interrupt enable) bits can be used to unmask the status interrupt for primary and secondary data errors.

In addition to data underflow and data overflow errors, the status interrupt is also triggered optionally when frame sync error is detected. The SPORT\_ERR\_A.FSERRMSK (frame sync error interrupt enable) bit unmask the status interrupt for this frame sync error. This frame sync error is generated because of premature frame sync, as explained in "Premature Frame sync error detection" section.

Note that a frame sync error is not detected in following cases.

- When there is no active data transmit/receive and the frame sync pulse occurs due to noise in the input signal.
- If there is an underflow or overflow error. SPORT error logic does not run (the bit count is not set and decremented) if there is an underflow error. Therefore, frame sync errors cannot be detected.
- When the frame sync pulse > system clock period.

The channel error status bits, SPORT\_CTL\_A.DERRPRI and SPORT\_CTL\_A.DERRSEC, in the control register are sticky read-only bits, which can be cleared in two ways:

- By disabling the SPORT (for frame sync error) or disabling the corresponding channel by itself (for SPORT\_CTL\_A.DERRPRI, SPORT\_CTL\_A.DERRSEC).
- By writing to R/W the SPORT\_ERR\_A.FSERRSTAT, SPORT\_ERR\_A.DERRPSTAT or SPORT\_ERR\_A.DERRSSTAT status bits.

When sticky bits are cleared, interrupts are also cleared.

## Interrupts

This section describes the various scenarios in which an interrupt is generated. Both the core and DMA are able to generate data interrupts for receive or transmit operations. Moreover, the SPORT modules generate error conditions which have a separate status interrupt.

## Internal Transfer Completion

Each SPORT half has an interrupt associated with it. Both primary and secondary data channels share the same interrupt vector, regardless of whether they are configured as a transmitter or receiver. To determine the source of an interrupt, applications should check the transmit or receive data buffer status (SPORT\_CTL\_A.DXSPRI, SPORT\_CTL\_A.DXSSEC) bits. In core mode, this interrupt signifies that either the transmit data buffer is empty (when SPORT\_CTL\_A.SPTRAN = 1) or new data is available in the receive data buffer (when SPORT\_CTL\_A.SPTRAN = 0). When serial port data packing is enabled (SPORT\_CTL\_A.PACK = 1), the transmit and receive interrupts are generated for 32-bit packed words, not for each 16-bit word.

The same interrupt can be used to indicate the completion of the transfer of a block of serial data when the serial ports are configured for DMA. The count register of DMA must be initialized with a word count that specifies the number of words to transfer. The count register decrements after each DMA transfer on the channel. When the word count reaches zero (or if a work unit has finished), the DMA completion interrupt is generated.

Multiple interrupts can occur if both data channels of serial port transmit or receive data in the same cycle. Any interrupt can be masked in the IMASK register.

## Transfer Finish Interrupt (TFI)

When a serial port in DMA mode is configured as a transmitter (SPORT\_CTL\_A.SPTRAN = 1), the Transmit Finish Interrupt feature can be used to signal the end of the transmission in a particular work unit. This feature can be enabled by setting SPORT\_CTL\_A.TFIENbit. When DMA transfers the last word to the FIFO, it also gives a signal to the SPORT indicating DMA has finished. The SPORT uses this information and then waits until all the data in the FIFO is transmitted out (including the transmit shift register) and generates the Transmit Finish Interrupt. The Interrupt Type field in the DMA Configuration register should be configured for Peripheral Interrupt.

## SPORT Register Descriptions

Serial Port (SPORT) contains the following registers.

**Table 26-15:** SPORT Module Registers

| Name         | Description                                       |
|--------------|---------------------------------------------------|
| SPORT_CTL_A  | Half SPORT 'A' Control Register                   |
| SPORT_DIV_A  | Half SPORT 'A' Divisor Register                   |
| SPORT_MCTL_A | Half SPORT 'A' Multi-channel Control Register     |
| SPORT_CS0_A  | Half SPORT 'A' Multi-channel 0-31 Select Register |

**Table 26-15:** SPORT Module Registers (Continued)

| Name          | Description                                         |
|---------------|-----------------------------------------------------|
| SPORT_CS1_A   | Half SPORT 'A' Multi-channel 32-63 Select Register  |
| SPORT_CS2_A   | Half SPORT 'A' Multi-channel 64-95 Select Register  |
| SPORT_CS3_A   | Half SPORT 'A' Multi-channel 96-127 Select Register |
| SPORT_ERR_A   | Half SPORT 'A' Error Register                       |
| SPORT_MSTAT_A | Half SPORT 'A' Multi-channel Status Register        |
| SPORT_CTL2_A  | Half SPORT 'A' Control 2 Register                   |
| SPORT_TXPRI_A | Half SPORT 'A' Tx Buffer (Primary) Register         |
| SPORT_RXPRI_A | Half SPORT 'A' Rx Buffer (Primary) Register         |
| SPORT_TXSEC_A | Half SPORT 'A' Tx Buffer (Secondary) Register       |
| SPORT_RXSEC_A | Half SPORT 'A' Rx Buffer (Secondary) Register       |
| SPORT_CTL_B   | Half SPORT 'B' Control Register                     |
| SPORT_DIV_B   | Half SPORT 'B' Divisor Register                     |
| SPORT_MCTL_B  | Half SPORT 'B' Multi-channel Control Register       |
| SPORT_CS0_B   | Half SPORT 'B' Multi-channel 0-31 Select Register   |
| SPORT_CS1_B   | Half SPORT 'B' Multi-channel 32-63 Select Register  |
| SPORT_CS2_B   | Half SPORT 'B' Multichannel 64-95 Select Register   |
| SPORT_CS3_B   | Half SPORT 'B' Multichannel 96-127 Select Register  |
| SPORT_ERR_B   | Half SPORT 'B' Error Register                       |
| SPORT_MSTAT_B | Half SPORT 'B' Multi-channel Status Register        |
| SPORT_CTL2_B  | Half SPORT 'B' Control 2 Register                   |
| SPORT_TXPRI_B | Half SPORT 'B' Tx Buffer (Primary) Register         |
| SPORT_RXPRI_B | Half SPORT 'B' Rx Buffer (Primary) Register         |

**Table 26-15:** SPORT Module Registers (Continued)

| Name          | Description                                   |
|---------------|-----------------------------------------------|
| SPORT_TXSEC_B | Half SPORT 'B' Tx Buffer (Secondary) Register |
| SPORT_RXSEC_B | Half SPORT 'B' Rx Buffer (Secondary) Register |

## Half SPORT 'A' Control Register

The SPORT\_CTL\_A contains transmit and receive control bits for SPORT half 'A', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in SPORT\_CTL\_A vary, depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

SPORT\_CTL\_A: Half SPORT 'A' Control Register - R/W

Reset = 0x0000 0000

Figure 26-15: SPORT\_CTL\_A Register Diagram

**Table 26-16:** SPORT\_CTL\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 29      | DERRPRI  | Data Error Status (Primary).<br>The SPORT_CTL_A.DERRPRI reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction.<br>If the SPORT_CTL_A.FSR bit =1, SPORT_CTL_A.DERRPRI indicates whether the SPORT_AFS signal (from an internal or external source) occurred while the SPORT_TXPRI_A data buffer was empty (during transmit) or the SPORT_RXPRI_A data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_AFS signal. It is important to note that, as a receiver, the SPORT_CTL_A.DERRPRI indicates when the channel has received new data while the SPORT_RXPRI_A receive buffer is full. This new data overwrites existing data.<br>If the SPORT_CTL_A.FSR bit =0, SPORT_CTL_A.DERRPRI is set whenever the SPORT is required to transmit while the SPORT_TXPRI_A transmit buffer is empty and is set whenever the SPORT is required to receive while the SPORT_RXPRI_A receive buffer is full.<br>The SPORT clears the SPORT_CTL_A.DERRPRI bit if the SPORT_ERR_A.DERRSTAT bit is cleared. |

| 26      | DERRSEC  | Data Error Status (Secondary).<br>The SPORT_CTL_A.DERRSEC reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction.<br>If the SPORT_CTL_A.FSR bit =1, SPORT_CTL_A.DERRSEC indicates whether the SPORT_AFS signal (from an internal or external source) occurred while the SPORT_TXSEC_A data buffer was empty (during transmit) or the SPORT_RXSEC_A data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_AFS signal. It is important to note that, as a receiver, the SPORT_CTL_A.DERRSEC indicates when the channel has received new data while the SPORT_RXSEC_A receive buffer is full. This new data overwrites existing data.<br>If the SPORT_CTL_A.FSR bit =0, SPORT_CTL_A.DERRSEC is set whenever the SPORT is required to transmit while the SPORT_TXSEC_A transmit buffer is empty and is set whenever the SPORT is required to receive while the SPORT_RXSEC_A receive buffer is full.<br>The SPORT clears the SPORT_CTL_A.DERRSEC bit if the SPORT_ERR_A.DERRSTAT bit is cleared. |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20      | TFIEN    | Transmit Finish Interrupt Enable.<br>The SPORT_CTL_A.TFIEN bit selects when the half SPORT issues its transmission complete interrupt if a DMA complete interrupt is enabled by the DDE_CFG_INT configuration. When enabled (SPORT_CTL_A.TFIEN =1), the DMA complete peripheral interrupt is generated when the last bit of last word in the DMA is shifted out. When disabled (SPORT_CTL_A.TFIEN =0), the DMA interrupt is generated when the DMA counter expires (the last word goes to the transmit buffer).                                                                                                                                             |
|         |          | 0 Last word sent (DMA count done) interrupt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1 Last bit sent (Tx buffer done) interrupt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 19      | FSED     | Frame Sync Edge Detect.<br>The SPORT_CTL_A.FSED bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The SPORT_CTL_A.FSED may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (SPORT_CTL_A.FSED =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.                                                                                                                                                                    |
|         |          | 0 Level detect frame sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|         |          | 1 Edge detect frame sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 18      | RJUST    | Right-Justified Operation Mode.<br>The SPORT_CTL_A.RJUST bit enables the half SPORT (if SPORT_CTL_A.OPMODE =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the SPORT_MCTL_A.WOFFSET field). For information about appropriate delay selections, see the SPORT operating modes section. |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 15      | DIFS     | Data-Independent Frame Sync.<br>The SPORT_CTL_A.DIFS bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by SPORT_DIV_A.FSDIV. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the SPORT_CTL_A.DIFS bit is automatically set when the half SPORT is in packed or multichannel modes. |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Data-dependent frame sync   |

|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| 12      | CKRE     | <p>Clock Rising Edge.</p> <p>The SPORT_CTL_A.CKRE selects the rising or falling edge of the SPORT_ACLK clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the SPORT_ACLK. Also note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for SPORT_CTL_A.CKRE. This programming drives the internally-generated signals on one edge of SPORT_ACLK and samples the received signals on the opposite edge.</p> |                                 |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Clock falling edge              |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Clock rising edge               |
| 11      | OPMODE   | <p>Operation mode.</p> <p>The SPORT_CTL_A.OPMODE bit selects whether the half SPORT operates in DSP standard / multi-channel mode or operates in I2S / packed / left-justified mode. The mode selection affects the operation of the SPORT_CTL_A.LAFS and SPORT_CTL_A.LFS bits. Also, the SPORT_CTL_A.OPMODE bit enables or disables operation of the SPORT_CTL_A.GCLKEN, SPORT_CTL_A.FSED, SPORT_CTL_A.RJUST, SPORT_CTL_A.DIFS, SPORT_CTL_A.FSR, and SPORT_CTL_A.CKRE bits.</p>                                                                                                          |                                 |

| 10      | ICLK     | Internal Clock.<br>When the half SPORT is in DSP standard mode (SPORT_CTL_A.OPMODE =0), the SPORT_CTL_A.ICLK bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the SPORT_ACLK clock signal, and the SPORT_ACLK is an output. The SPORT_DIV_A.CLKDIV serial clock divisor value determines the clock frequency. For internal clock disabled, the SPORT_ACLK clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.                                                                                                                                                                                                                                                           |
|         |          | 0 External clock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         |          | 1 Internal clock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 9       | PACK     | Packing Enable.<br>The SPORT_CTL_A.PACK bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15-0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31-16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word. |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16   | FSDIV    | <p>Frame Sync Divisor.</p> <p>The SPORT_DIV_A.FSDIV bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating SPORT_DIV_A.FSDIV to the number of cycles between frame sync pulses is:</p> <p><math>SPORT\_DIV\_A.FSDIV = (\text{number of serial clocks between frame syncs}) - 1</math></p> <p>Use the following equation to determine the value of SPORT_DIV_A.FSDIV, given the serial clock frequency and desired frame sync frequency:</p> <p><math>FSDIV = (SCLK / FSCLK) - 1</math></p> <p>Note that the frame sync is continuously active when <math>SPORT\_DIV\_A.FSDIV = 0</math>. The value of SPORT_DIV_A.FSDIV should not be less than the serial word length (SPORT_CTL_A.SLEN), as this may cause an external device to abort the current operation or cause other unpredictable results.</p> |

| 15:0    | CLKDIV   | <p>Clock Divisor.</p> <p>The SPORT_DIV_A.CLKDIV bits select the divisor that the half SPORT uses to calculate the serial clock (SPORT_ACLK) from the processor system clock (SCLK1). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (SPORT_CTL_A.ICLK=1), legal SPORT_DIV_A.CLKDIV values are 0 to 65535. Given the processor system clock 1 frequency and desired serial clock frequency, use the following formula to calculate the value of SPORT_DIV_A.CLKDIV:</p> $\text{CLKDIV} = (\text{SCLK1} / \text{SPORT\_ACLK}) - 1$ <p>For the maximum serial clock frequency, see the processor data sheet.</p> |

## Half SPORT 'A' Multi-channel Control Register

The SPORT\_MCTL\_A register controls the half SPORT's multi-channel operations. This register enables multi-channel operation, enables multi-channel data packing, selects the multi-channel frame delay, selects the number of multi-channel slots, and selects the multi-channel window offset size.

| 25:16   | WOFFSET  | <p>Window Offset.</p> <p>The SPORT_MCTL_A.WOFFSET bits select the start location for the half SPORT's active window of channels within the 1024-channel range. A value of 0 specifies no offset and 896 is the largest value that permits using all 128 channels. When multi-channel mode is disabled (SPORT_MCTL_A.MCE =0)and right-justified mode is enabled (SPORT_CTL_A.RJUST =1), the least significant 6 bits of SPORT_MCTL_A.WOFFSET serve as the delay count (DCNT) field. These bits introduce a clock delay before the half SPORT state machine starts to capture data. For information about appropriate delay selections, see the SPORT operating modes section.</p> |         |
| 14:8    | WSIZE    | <p>Window Size.</p> <p>The SPORT_MCTL_A.WSIZE bits select the window size for the half SPORT's active window of channels. Use the following formula to calculate the window size value:</p> <p>SPORT_MCTL_A.WSIZE = (number of channel slots) -1</p>                                                                                                                                                                                                                                                                                                                                                                                                                             |         |
| 7:4     | MFD      | <p>Multi-channel Frame Delay.</p> <p>The SPORT_MCTL_A.MFD bits select the delay (in serial clock cycles) between the half SPORT's multi-channel frame sync pulse and channel 0. The 4-bit field allows selecting Multichannel Frame delay of 0-15 serial clocks.</p>                                                                                                                                                                                                                                                                                                                                                                                                             |         |
| 2       | MCPDE    | <p>Multi-Channel Packing DMA Enable.</p> <p>The SPORT_MCTL_A.MCPDE bit enables DMA data packing for transmit and enables DMA data unpacking for the half SPORT's multi-channel data transfers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | MCE      | Multichannel enable.<br>The SPORT_MCTL_A.MCE bit enables multi-channel operations for the half SPORT. The Half SPORT is configured in normal multichannel mode if SPORT_CTL_A.OPMODE=0; while it is configured in Packed mode if SPORT_CTL_A.OPMODE=1. When Configuring in these modes, the Multichannel Enable bit (SPORT_MCTL_A.MCE) should be set before enabling SPORT data channel enable bits (SPORT_CTL_A.SPENPRI and/or SPORT_CTL_A.SPENSEC). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared (requires 6 CCLK cycles), and the SPORT_CTL_A.DERRPRI and SPORT_CTL_A.DERRSEC bits are cleared. |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         |          | 1      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Half SPORT 'A' Multi-channel 0-31 Select Register

The SPORT\_CS0\_A register's bits (when set, =1) each corresponds to an active channel for the half SPORT in multi-channel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register de-activates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

**SPORT\_CS0\_A: Half SPORT 'A' Multi-channel 0-31 Select Register - R/W**

Reset = 0x0000 0000

**Figure 26-18:** SPORT\_CS0\_A Register Diagram

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                |
|---------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| 6       | FSERRSTAT | Frame Sync Error Status.<br>The SPORT_ERR_A.FSERRSTAT bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, SPORT_CTL_A.SLEN = 32). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur during a zero bit count. |                                                |
|         |           | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | No error                                       |
|         |           | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Error (non-zero bit count at frame sync)       |
| 5       | DERRSSTAT | Data Error Secondary Status.<br>The SPORT_ERR_A.DERRSSTAT bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (SPORT_CTL_A.SPTRAN =1), SPORT_ERR_A.DERRSSTAT indicates transmit underflow status. During receive (SPORT_CTL_A.SPTRAN =0), SPORT_ERR_A.DERRSSTAT indicates receive overflow status. This bit is used to clear the latch of SPORT status interrupt when triggered by secondary Data Error. This bit can also be used to clear the read-only SPORT_CTL_A.DERRSEC status bit.                                                                                                                                                                                            |                                                |
|         |           | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | No error                                       |

## Half SPORT 'A' Multi-channel Status Register

The SPORT\_MSTAT\_A register indicates the current multi-channel being serviced among the half SPORT's active channels in multi-channel mode. The half SPORT increments the value by one in this register as each channel is serviced. The value in the SPORT\_MSTAT\_A register restarts at 0 at each frame sync.

**SPORT\_MSTAT\_A: Half SPORT 'A' Multi-channel Status Register - R/NW**

## Half SPORT 'A' Tx Buffer (Primary) Register

The SPORT\_TXPRI\_A register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core may load the data into the buffer (word-by-word process) or the DMA controller may automatically load the data into the buffer (DMA process).

The SPORT\_TXPRI\_A register acts as a three location buffer if SPORT data packing is disabled (SPORT\_CTL\_A.PACK=0); while it acts as two location buffer when packing is enabled (SPORT\_CTL\_A.PACK=1). So depending on PACK bit setting, two 32-bit words or three 32-bit words may be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT\_TXPRI\_A register contents are automatically loaded into the output shifter. The half SPORT may issue an interrupt (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt does not occur when the half SPORT is executing a DMA-based transfer, and the interrupt may be masked depending how its trigger output is configured in the TRU\_SSRn registers or TRU\_MTR register.

For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions. |

## Half SPORT 'A' Rx Buffer (Primary) Register

The SPORT\_RXPRI\_A register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. When configured as a receiver, the half SPORT automatically loads the SPORT\_RXPRI\_A register from the receive shifter after a complete word has been received. The half SPORT then loads the data to internal memory through the DMA controller (DMA process) or through the SPORT process of a program running on the processor core (word-by-word process). With a data buffer and input shift register, SPORT\_RXPRI\_A register acts as a two-location buffer. Therefore SPORT can keep Two 32-bit received words at max in any one time (independent of SPORT\_CTL\_A.PACK bit setting).

Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions. |

Half SPORT 'A' Tx Buffer (Secondary) Register

The SPORT\_TXSEC\_A register buffers the half SPORT's secondary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the secondary channel. Either a program running on the processor core may load the data into the buffer (word-by-word process) or the DMA controller may automatically load the data into the buffer (DMA process).

The SPORT\_TXSEC\_A register acts as a three location buffer if SPORT data packing is disabled (SPORT\_CTL\_A.PACK=0); while it acts as two location buffer when packing is enabled (SPORT\_CTL\_A.PACK=1). So depending on PACK bit setting, two 32-bit words or three 32-bit words may be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT\_TXSEC\_A register contents are automatically loaded into the output shifter. The half SPORT may issue an interrupt (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt does not occur when the half SPORT is executing a DMA-based transfer, and the interrupt may be masked depending how its trigger output is configured in the TRU\_SSRn registers or TRU\_MTR register.

| 31:0    | VALUE    | Receive Buffer (Secondary).<br>The SPORT_RXSEC_A.VALUE bits hold the half SPORT's secondary channel receive data. Note that changes to the half SPORT operation mode (for example, toggling the SPORT_MCTL_A.MCE) empty the contents of this data buffer. For more information, see the SPORT_CTL_A and SPORT_MCTL_A register descriptions. |

Half SPORT 'B' Control Register

The SPORT\_CTL\_B contains transmit and receive control bits for SPORT half 'B', including serial port mode selection for the half SPORT's primary and secondary channels. The function of some bits in SPORT\_CTL\_B vary, depending on the SPORT's operating mode. For more information, see the SPORT operating modes description. If reading reserved bits, the read value is the last written value to these bits or is the reset value of these bits.

**SPORT\_CTL\_B: Half SPORT 'B' Control Register - R/W**

Reset = 0x0000 0000

| 29      | DERRPRI  | Data Error Status (Primary).<br>The SPORT_CTL_B.DERRPRI reports the half SPORT's primary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction.<br>If the SPORT_CTL_B.FSR bit =1, SPORT_CTL_B.DERRPRI indicates whether the SPORT_BFS signal (from an internal or external source) occurred while the SPORT_TXPRI_B data buffer was empty (during transmit) or the SPORT_RXPRI_B data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_BFS signal. It is important to note that, as a receiver, the SPORT_CTL_B.DERRPRI indicates when the channel has received new data while the SPORT_RXPRI_B receive buffer is full. This new data overwrites existing data.<br>If the SPORT_CTL_B.FSR bit =0, SPORT_CTL_B.DERRPRI is set whenever the SPORT is required to transmit while the SPORT_TXPRI_B transmit buffer is empty and is set whenever the SPORT is required to receive while the SPORT_RXPRI_B receive buffer is full.<br>The SPORT clears the SPORT_CTL_B.DERRPRI bit if the SPORT_ERR_B.DERRSTAT bit is cleared. |
|         |          | 0 No error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1 Error (Tx underflow or Rx overflow)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 26      | DERRSEC  | Data Error Status (Secondary).<br>The SPORT_CTL_B.DERRSEC reports the half SPORT's secondary channel transmit underflow status or receive overflow status, depending on the SPORT transfer direction.<br>If the SPORT_CTL_B.FSR bit =1, SPORT_CTL_B.DERRSEC indicates whether the SPORT_BFS signal (from an internal or external source) occurred while the SPORT_TXSEC_B data buffer was empty (during transmit) or the SPORT_RXSEC_B data buffer was full (during receive). The SPORT transmits or receives data whenever it detects the SPORT_BFS signal. It is important to note that, as a receiver, the SPORT_CTL_B.DERRSEC indicates when the channel has received new data while the SPORT_RXSEC_B receive buffer is full. This new data overwrites existing data.<br>If the SPORT_CTL_B.FSR bit =0, SPORT_CTL_B.DERRSEC is set whenever the SPORT is required to transmit while the SPORT_TXSEC_B transmit buffer is empty and is set whenever the SPORT is required to receive while the SPORT_RXSEC_B receive buffer is full.<br>The SPORT clears the SPORT_CTL_B.DERRSEC bit if the SPORT_ERR_B.DERRSTAT bit is cleared. |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20      | TFIEN    | Transmit Finish Interrupt Enable.<br>The SPORT_CTL_B.TFIEN bit selects when the half SPORT issues its transmission complete interrupt if a DMA complete interrupt is enabled by the DDE_CFG_INT configuration. When enabled (SPORT_CTL_B.TFIEN =1), the DMA complete peripheral interrupt is generated when the last bit of last word in the DMA is shifted out. When disabled (SPORT_CTL_B.TFIEN =0), the DMA interrupt is generated when the DMA counter expires (the last word goes to the transmit buffer).                                                                                                                                             |
|         |          | 0 Last word sent (DMA count done) interrupt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1 Last bit sent (Tx buffer done) interrupt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 19      | FSED     | Frame Sync Edge Detect.<br>The SPORT_CTL_B.FSED bit enables the half SPORT to start transmitting or receiving after detecting an active edge of an external frame sync. The SPORT_CTL_B.FSED may be enabled even during an active frame sync, and the half SPORT starts the transfer on the next valid rising or falling edge of external frame sync. If disabled (SPORT_CTL_B.FSED =0), the half SPORT operates in the standard level-sensitive detection mode for external frame sync.                                                                                                                                                                    |
|         |          | 0 Level detect frame sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|         |          | 1 Edge detect frame sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 18      | RJUST    | Right-Justified Operation Mode.<br>The SPORT_CTL_B.RJUST bit enables the half SPORT (if SPORT_CTL_B.OPMODE =1) to transfer data in right-justified operation mode. In this mode, the half SPORT aligns data to the end of the frame sync, rather than the start of the frame sync. When using right-justified mode, systems should program an appropriate delay count to introduce a clock delay before the half SPORT state machine starts to capture data. This value is set in the DCNT field (right-justified mode usage of the SPORT_MCTL_B.WOFFSET field). For information about appropriate delay selections, see the SPORT operating modes section. |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 15      | DIFS     | Data-Independent Frame Sync.<br>The SPORT_CTL_B.DIFS bit selects whether the half SPORT uses a data-independent or data-dependent frame sync. When using a data-independent frame sync, the half SPORT generates the sync at the interval selected by SPORT_DIV_B.FSDIV. When using a data-dependent frame sync, the half SPORT generates the sync on the selected interval when the transmit buffer is not empty or when the receive buffer is not full. Note that the SPORT_CTL_B.DIFS bit is automatically set when the half SPORT is in packed or multichannel modes. |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Data-dependent frame sync   |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Data-independent frame sync |
| 14      | IFS      | Internal Frame Sync.<br>The SPORT_CTL_B.IFS bit selects whether the half SPORT uses an internal frame sync or uses an external frame sync.<br>Note that the externally-generated frame sync does not need to be synchronous with the processor's system clock.                                                                                                                                                                                                                                                                                                            |                             |

|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| 12      | CKRE     | Clock Rising Edge.<br>The SPORT_CTL_B.CKRE selects the rising or falling edge of the SPORT_BCLK clock for the half SPORT to sample receive data and frame sync. Note that the half SPORT changes the state of transmit data and frame sync signals on the non-selected edge of the SPORT_BCLK. Also note that the transmit and receive related SPORT halves (A and B) should be programmed with the same value for SPORT_CTL_B.CKRE. This programming drives the internally-generated signals on one edge of SPORT_BCLK and samples the received signals on the opposite edge. |                                 |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Clock falling edge              |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Clock rising edge               |
| 11      | OPMODE   | Operation mode.<br>The SPORT_CTL_B.OPMODE bit selects whether the half SPORT operates in DSP standard / multi-channel mode or operates in I2S / packed / left-justified mode. The mode selection affects the operation of the SPORT_CTL_B.LAFS and SPORT_CTL_B.LFS bits. Also, the SPORT_CTL_B.OPMODE bit enables or disables operation of the SPORT_CTL_B.GCLKEN, SPORT_CTL_B.FSED, SPORT_CTL_B.RJUST, SPORT_CTL_B.DIFS, SPORT_CTL_B.FSR, and SPORT_CTL_B.CKRE bits.                                                                                                          |                                 |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | DSP standard/multi-channel mode |

|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| 10      | ICLK     | Internal Clock.<br>When the half SPORT is in DSP standard mode (SPORT_CTL_B.OPMODE =0), the SPORT_CTL_B.ICLK bit selects whether the half SPORT uses an internal or external clock. For internal clock enabled, the half SPORT generates the SPORT_BCLK clock signal, and the SPORT_BCLK is an output. The SPORT_DIV_B.CLKDIV serial clock divisor value determines the clock frequency. For internal clock disabled, the SPORT_BCLK clock signal is an input, and the serial clock divisor is ignored. Note that the externally-generated serial clock does not need to be synchronous with the processor's system clock.                                                                                                                                                                                                                                                           |                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | External clock |

| 9       | PACK     | Packing Enable.<br>The SPORT_CTL_B.PACK bit enables the half SPORT to perform 16- to 32-bit packing on received data and to perform 32- to 16-bit unpacking on transmitted data. The receive packing operation packs two successive received words into a single 32-bit word. The transmit unpacking operation unpacks each 32-bit word and transmits it as two 16-bit words. The first 16-bit (or smaller) word is right-justified in bits 15-0 of the packed word, and the second 16-bit (or smaller) word is right-justified in bits 31-16. This format applies to both receive (packing) and transmit (unpacking) operations. Companding may be used with word packing or unpacking. The half SPORT generates data transfer related interrupts when packing is enabled. The transmit and receive interrupts are generated for the 32-bit packed words, not for each 16-bit word. |                |

## Half SPORT 'B' Divisor Register

The SPORT\_DIV\_B contains divisor values that determine frequencies of internally-generated clocks and frame syncs for SPORT half 'B'.

**SPORT\_DIV\_B: Half SPORT 'B' Divisor Register - R/W**

Reset = 0x0000 0000

**Figure 26-30:** SPORT\_DIV\_B Register Diagram

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16   | FSDIV    | <p>Frame Sync Divisor.</p> <p>The SPORT_DIV_B.FSDIV bits select the number of transmit or receive clock cycles that the half SPORT counts before generating a frame sync pulse. The half SPORT counts serial clock cycles whether these are from an internally- or an externally-generated serial clock. The formula relating SPORT_DIV_B.FSDIV to the number of cycles between frame sync pulses is:</p> $\text{SPORT\_DIV\_B.FSDIV} = (\text{number of serial clocks between frame syncs}) - 1$ <p>Use the following equation to determine the value of SPORT_DIV_B.FSDIV, given the serial clock frequency and desired frame sync frequency:</p> $\text{FSDIV} = (\text{SCLK} / \text{FSCLK}) - 1$ <p>Note that the frame sync is continuously active when SPORT_DIV_B.FSDIV = 0. The value of SPORT_DIV_B.FSDIV should not be less than the serial word length (SPORT_CTL_B.SLEN), as this may cause an external device to abort the current operation or cause other unpredictable results.</p> |

Table 26-31: SPORT\_DIV\_B Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | CLKDIV   | <p>Clock Divisor.</p> <p>The SPORT_DIV_B.CLKDIV bits select the divisor that the half SPORT uses to calculate the serial clock (SPORT_BCLK) from the processor system clock (SCLK1). The divisor is a 16-bit value, allowing a wide range of serial clock rates. When configured for internal clock (SPORT_CTL_B.ICLK =1), legal SPORT_DIV_B.CLKDIV values are 0 to 65535. Given the processor system clock 1 frequency and desired serial clock frequency, use the following formula to calculate the value of SPORT_DIV_B.CLKDIV:</p> $\text{CLKDIV} = (\text{SCLK1} / \text{SPORT\_BCLK}) - 1$ <p>For the maximum serial clock frequency, see the processor data sheet.</p> |

Half SPORT 'B' Multi-channel Control Register

The SPORT\_MCTL\_B register controls the half SPORT's multi-channel operations. This register enables multi-channel operation, enables multi-channel data packing, selects the multi-channel frame delay, selects the number of multi-channel slots, and selects the multi-channel window offset size.

Figure 26-31: SPORT\_MCTL\_B Register Diagram

**Table 26-32:** SPORT\_MCTL\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 25:16   | WOFFSET  | Window Offset.<br>The SPORT_MCTL_B.WOFFSET bits select the start location for the half SPORT's active window of channels within the 1024-channel range. A value of 0 specifies no offset and 896 is the largest value that permits using all 128 channels. When multi-channel mode is disabled (SPORT_MCTL_B.MCE =0)and right-justified mode is enabled (SPORT_CTL_B.RJUST =1), the least significant 6 bits of SPORT_MCTL_B.WOFFSET serve as the delay count (DCNT) field. These bits introduce a clock delay before the half SPORT state machine starts to capture data. For information about appropriate delay selections, see the SPORT operating modes section. |         |
| 14:8    | WSIZE    | Window Size.<br>The SPORT_MCTL_B.WSIZE bits select the window size for the half SPORT's active window of channels. Use the following formula to calculate the window size value:<br>SPORT_MCTL_B.WSIZE = (number of channel slots) -1                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |
| 7:4     | MFD      | Multi-channel Frame Delay.<br>The SPORT_MCTL_B.MFD bits select the delay (in serial clock cycles) between the half SPORT's multi-channel frame sync pulse and channel 0. The 4-bit field allows selecting Multichannel Frame delay of 0-15 serial clocks.                                                                                                                                                                                                                                                                                                                                                                                                             |         |
| 2       | MCPDE    | Multi-Channel Packing DMA Enable.<br>The SPORT_MCTL_B.MCPDE bit enables DMA data packing for transmit and enables DMA data unpacking for the half SPORT's multi-channel data transfers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |         |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Disable |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Enable  |

Table 26-32: SPORT\_MCTL\_B Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | MCE      | Multi-Channel Enable.<br>The SPORT_MCTL_B.MCE bit enables multi-channel operations for the half SPORT. The Half SPORT is configured in normal multichannel mode if SPORT_CTL_B.OPMODE=0; while it is configured in Packed mode if SPORT_CTL_B.OPMODE=1. When Configuring in these modes, the Multichannel Enable bit (SPORT_MCTL_B.MCE) should be set before enabling SPORT data channel enable bits (SPORT_CTL_B.SPENPRI and/or SPORT_CTL_B.SPENSEC). When these channel bits transition from 1 to 0, note that the half SPORT's data transfer buffers are cleared (requires 6 CCLK cycles), and the SPORT_CTL_B.DERRPRI and SPORT_CTL_B.DERRSEC bits are cleared. |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Half SPORT 'B' Multi-channel 0-31 Select Register

The SPORT\_CS0\_B register's bits (when set, =1) each corresponds to an active channel for the half SPORT in multi-channel mode. When the register activates a channel (corresponding bit =1), the half SPORT transmits or receives the word in that channel's position of the data stream. When the register de-activates a channel (corresponding bit =0), the half SPORT either three-states its data transmit pin (during the channel's transmit time slot) or ignores incoming data (during the channel's receive time slot).

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                |
|---------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| 6       | FSERRSTAT | Frame Sync Error Status.<br>The SPORT_ERR_B.FSERRSTAT bit indicates that the half SPORT has detected a frame sync when the bit count (bits remaining in the frame) is non-zero. When a half SPORT is receiving or transmitting, its bit count is set to a word length (for example, SPORT_CTL_B.SLEN = 32). After each serial clock edge, the half SPORT decrements the transfer's bit count. After the word is received or transmitted, the transfer's bit count reaches zero, and the half SPORT resets it (for example, to 32) on next frame sync. Normal SPORT data transfers always have a non-zero bit count value when active transmission or reception is occurring. Normal SPORT frame syncs occur during a zero bit count. |                                                |
|         |           | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | No error                                       |
|         |           | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Error (non-zero bit count at frame sync)       |
| 5       | DERRSSTAT | Data Error Secondary Status.<br>The SPORT_ERR_B.DERRSSTAT bit indicates the error status for the half SPORT's secondary channel data buffers. During transmit (SPORT_CTL_B.SPTRAN =1), SPORT_ERR_B.DERRSSTAT indicates transmit underflow status. During receive (SPORT_CTL_B.SPTRAN =0), SPORT_ERR_B.DERRSSTAT indicates receive overflow status. This bit is used to clear the latch of SPORT status interrupt when triggered by secondary Data Error. This bit can also be used to clear the read-only SPORT_CTL_B.DERRSEC status bit.                                                                                                                                                                                            |                                                |
|         |           | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | No error                                       |

## Half SPORT 'B' Multi-channel Status Register

The SPORT\_MSTAT\_B register indicates the current multi-channel being serviced among the half SPORT's active channels in multi-channel mode. The half SPORT increments the value by one in this register as each channel is serviced. The value in the SPORT\_MSTAT\_B register restarts at 0 at each frame sync.

## Half SPORT 'B' Tx Buffer (Primary) Register

The SPORT\_TXPRI\_B register buffers the half SPORT's primary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the primary channel. Either a program running on the processor core may load the data into the buffer (word-by-word process) or the DMA controller may automatically load the data into the buffer (DMA process).

The SPORT\_TXPRI\_B register acts as a three location buffer if SPORT data packing is disabled (SPORT\_CTL\_B.PACK=0); while it acts as two location buffer when packing is enabled (SPORT\_CTL\_B.PACK=1). So depending on PACK bit setting, two 32-bit words or three 32-bit words may be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT\_TXPRI\_B register contents are automatically loaded into the output shifter. The half SPORT may issue an interrupt (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt does not occur when the half SPORT is executing a DMA-based transfer, and the interrupt may be masked depending how its trigger output is configured in the TRU\_SSRn registers or TRU\_MTR register.

For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions. |

Half SPORT 'B' Rx Buffer (Primary) Register

The SPORT\_RXPRI\_B register buffers the half SPORT's primary channel receive data. This buffer becomes active when the half SPORT is configured to receive data on the primary channel. When configured as a receiver, the half SPORT automatically loads the SPORT\_RXPRI\_B register from the receive shifter after a complete word has been received. The half SPORT then loads the data to internal memory through the DMA controller (DMA process) or through the SPORT process of a program running on the processor core (word-by-word process). With a data buffer and input shift register, SPORT\_RXPRI\_B register acts as a two-location buffer. Therefore SPORT can keep Two 32-bit received words at max in any one time (independent of SPORT\_CTL\_B.PACK bit setting).

For more information, see the SPORT_CTL_B and SPORT_MCTL_B register descriptions. |

## Half SPORT 'B' Tx Buffer (Secondary) Register

The SPORT\_TXSEC\_B register buffers the half SPORT's secondary channel transmit data. This register must be loaded with the data to be transmitted if the half SPORT is configured to transmit on the secondary channel. Either a program running on the processor core may load the data into the buffer (word-by-word process) or the DMA controller may automatically load the data into the buffer (DMA process).

The SPORT\_TXSEC\_B register acts as a three location buffer if SPORT data packing is disabled (SPORT\_CTL\_B.PACK =0); while it acts as two location buffer when packing is enabled (SPORT\_CTL\_B.PACK =1). So depending on PACK bit setting, two 32-bit words or three 32-bit words may be stored in the transmit queue at any time. When the transmit register is loaded and any previous word has been transmitted, the SPORT\_TXSEC\_B register contents are automatically loaded into the output shifter. The half SPORT may issue an interrupt (transmit buffer is not full) when it has loaded the output transmit shifter, signifying that the transmit buffer is ready to accept the next word. This interrupt does not occur when the half SPORT is executing a DMA-based transfer, and the interrupt may be masked depending how its trigger output is configured in the TRU\_SSRn registers or TRU\_MTR register.

## 27 ADC Control Module (ACM)

The processor includes an ADC control module (ACM) that provides an interface that synchronizes the controls between the processor and an Analog-to-Digital Converter (ADC). The analog-to-digital conversions are initiated by the processor, based on either external or internal events.

Traditionally, ADC sampling uses processor interrupts (initiated by the events) and the interrupt service routine programming of the appropriate peripheral (usually SPORT or SPI) for initiating the ADC conversion process. This traditional approach has some limiting factors:

- The ADC sampling instances are not precisely controlled due to interrupt latencies (which can vary) or due to variable instruction execution cycles
- Consumption of processor MIPS can be prohibitive, especially for high frequency of conversion related events.
- If the ADC requires any control signals (such as channel select pins, ADC mode select, ADC Range pin) with some specified Set-up, Hold or Zero time requirements with respect to sampling time, then providing such signals with GP flags may be difficult to implement in the application.

The ADC control module (ACM) answers the limitations of the traditional approach to sampling by providing a dedicated hardware, which samples the events and provides sampling signals with required timings to the ADC in real-time. It permits flexible scheduling of sampling instants and provides precise sampling signals to the ADC. The ACM approach both saves processor bandwidth and provides precise control for ADC sampling time. Furthermore, the processor can be interfaced directly to many ADCs without any glue logic required.

The ACM synchronizes the ADC conversion process (by providing ADC clock, ADC conversion start signal, and related ADC controls), but the actual data acquisition from the ADC is accomplished by other peripheral such as SPORT. On the ADSP-BF60x processors, the ADC module can be used in conjunction with either halves of SPORT1. The processor does not support ACM operation with the SPI. The following figure shows how an ADC can be interfaced using ACM and SPORT peripherals of processor.

**Figure 27-1:** ADC/SPORT Interface

The ADSP-BF60x processors do not incorporate on-chip internal ADC.

## ACM Features

The ADC Control Module (ACM) offers following features and capabilities:

- Provides serial clock, chip select and five general-purpose control lines to control the ADC operations. Internally routes clock and CS signals to selected serial port.
- ACM can accept four trigger inputs, based on which it can precisely initiate the ADC sampling events. The Trigger inputs may be internally generated or externally supplied. Further, polarity of trigger inputs is configurable.
- ACM can handle 16 ADC sampling events per valid trigger received. Each event can be independently programmed to specify when to initiate ADC sampling with respect to trigger input.
- Two independent 32-bit ACM Timers can be used to divide 16 events into two groups of 8 events each.
- Automatically stops the ACM Timer after completion of associated events in order to save the power.
- Four-deep pending FIFO to queue the active events when ACM is busy.
- ACM can internally generate serial clock up to  $SCLK/2$  rate. Improved granularity for internal clock generation, allowing both odd and even  $SCLK:ACLK$  ratios.
- ACM clock can be gated (active only during enabled events) to interface it with SPI-compatible ADC's.
- When initiating ADC sampling cycle, the width of chip select signal-which can be also used by ADC as start of conversion-, can be configured from 1  $ACLK$  to 256  $ACLK$ s. Further the polarity of this signal can be configured as active-high or active-low signal.

- Auto ACLK adjustment at the time of CS assertion. After assertion of CS signal, the first edge of ACLK can be configured to be either rising edge or falling edge.
- The five general-purpose control lines provided by ACM can be programmed for required Set-up and Hold time with respect to ADC sampling cycle. Additionally, Zero time can be inserted between two successive sampling cycles.
- ACM provides 16 Event Order registers (one per each event) which indicates the order at which events were handled. Optionally these registers can be automatically cleared by ACM's trigger input.
- The ACM hardware flags the appropriate event completion status bit upon completion of an event. If an event got missed, appropriate event missed status bit is flagged. Each event has separate bits. Optionally Event Completion Interrupt and Event Missed Interrupt can be triggered upon these respective conditions.
- Predictable latency between the internal occurrence of an event and the assertion of a sampling event.
- ACM can operate as Trigger Master to provide signal to TRU upon completion of events.

## ACM Functional Description

The ADC Control Module uses internal ACM timers and the event time register to create events. The user has to enable one of the timer (or both timers) for the ACM operation. Appropriate event control register and event time register values also have to be programmed. After receiving valid trigger on selected trigger input, the timer starts counting. If at anytime the timer count matches with the time specified in the event time register (ACM\_ETx) of an enabled event (associated with that timer), the comparators generate an active event signal to the timing generation unit to start the ADC access. The counter continues counting, and for each matching with enabled event time, the ACM gives an event signal to the timing generation unit.

Figure shows the ACM operation where only two events (Event0 and Event3) are enabled. The line labeled “ADC Controls” depicts the timing of the ADC control signals: A[4:0].

**Figure 27-2:** ACM Operation, Two Events

Note that, this figure depicts a usage case in which ACM Event3 Time register is programmed with a count value that is greater than that programmed in Event0. So, Event3 occurs after Event0. There are, however, no restrictions on the order of the different events. Event0 time can be greater than, less than or equal to Event3 time.

If value in Event0 Time register is less than the value in Event3 Time, Event3 occurs after Event0; while if the value in Event0 is greater than the value in Event3, then Event3 occurs before Event0. Whereas if Event0 time is equal to the Event3 time, the events are processed according to their priorities. Only the highest priority event is processed, and other lower priority event is missed (even if there is a space in pending event FIFO), as both events, are handled by same ACM Timer. Event0 has the highest priority. So in this case, the timing generation unit processes Event0, while Event3 is missed. In this case, the Event3 missed status bit (EM3) is set in the missed event status register (ACM\_MEVSTAT), and the Event Missed bit (EMISS) is set in the ACM Status (ACM\_STAT) register, indicating that an event has been missed.

If event times are not sufficiently spaced apart, an event could occur while a previous event is underway (while the CS of the previous event is asserted). In this situation, the second event is queued in the pending event FIFO. If the pending event FIFO is full, the event will not get queued and will be missed. This can happen mostly when enabling both ACM Timers with different trigger inputs and the sources of these triggers are not synchronized together. In this case, it is possible that the events controlled by the two timers to overlap. It is therefore important to consider the possibility of events occurring either simultaneously or being missed when enabling events on two asynchronously-triggered timers. It is programmer's responsibility to ensure that the values in the event time registers do not lead to event misses. The appropriate event miss bit in the ACM\_MEVSTAT and ACM\_STAT registers will be flagged, upon missing any event.

When both ACM timers are enabled, and if they triggered the events simultaneously, the event triggered by ACMTMR0 is given higher priority. For example, when an ACMTMR0 event (one of events 0 through 7) and ACMTMR1 event (one of events 8 through 15) occur simultaneously, the ACMTMR0 event is processed by the timing generation unit or is queued in the pending event FIFO before the processing or the queuing of the ACMTMR1 event.

When all the events enabled for a given ACM timer (ACMTMR<sub>x</sub>) are processed, the ACM timer stops incrementing. (Note that this timer action is not reflected in Figure). And corresponding Event Completion bit (ECOMP<sub>x</sub>) in the ACM Status register is flagged. The same bit also reflects in Event Completion Status register (ACM\_EVSTAT), which can optionally generate Event Completion interrupt if the corresponding bit in the Event Completion Interrupt mask register (ACM\_EVMSK) is set. Two separate bits are available, one for each ACM Timer.

The ACM can be used to generate various sequences of ADC sampling events through appropriate programming of event time registers, event control registers, and triggers. For more information, see the usage cases described in [Emulation Mode Use Case](#).

## ACM Event Handling Latency

The ACM ensures a predictable latency between the internal occurrence of an event (event time value matching the ACM timer count value) and the assertion of a sampling event by the timing generation unit (the assertion of CS and other ACM signals as appropriate).

Latency between occurrence of Event to CS assertion = ( $t_S + t_{ED}$ ) SCLK1 cycles, where:

- $t_S$  = ADC control setup cycles programmed in ACM\_TCO register
- $t_{ED}$  = 1 SCLK cycle latency

This predictable latency is applicable only when events are generated when the Timing Generation Unit is idle. If this Timing Generation Unit was processing a prior sampling event, then the new event is held in the Pending Event FIFO, and the latency is increase by the duration that the new event is held in the pending event FIFO.

If an external trigger input is selected as a trigger input of the ACM, then synchronization to this external signal leads to a 3 SCLK cycle fixed delay and 1 SCLK cycle variability due to delays in latching asynchronous external triggers. When the external trigger is synchronous to SCLK, the 1 SCLK cycle variability is eliminated and the latency from the external trigger to the start of the count of an ACM timer becomes fixed at 3 SCLK cycles. This latency is denoted as  $t_{TRIG}$ .

As a result, the total latency between an external trigger and the assertion of an ADC sampling event, assuming that the sampling event does is not queued in the pending event FIFO, is:

$$\text{Total Latency} = t_{TRIG} + t_{ED} + t_{PD} + t_S$$

The following figure shows latency details from the occurrence of external triggers to the assertion of ADC sampling events.

In the following figure, observe the following timing definitions:

- $t_{TRIG}$  = trigger to timer start delay (3 to 4 SCLK)
- $t_{PD}$  = Event Time (programmed in ACM\_ETx register of event).
- $t_{ED}$  = internal event delay (1 SCLK)
- $t_S$  = set up time (programmed in ACM\_TC0 register)
- $t_{CSW}$  = CS width (programmed in ACM\_TC0 register)
- $t_H$  = hold time (programmed in ACM\_TC1 register)

**Figure 27-3:** Latency of External Triggers to Assertion of ADC Sampling Events

## ACM Timing Specifications

The AC timing of the ACM signals are specified in the ADSP-BF60x Embedded Processor Data Sheet. When trigger sources external to the processor are used for triggering the ACM (for example, external signals on the GPIO, timer or PWM sync pins), the minimum pulse-width for such trigger sources needs to be greater than one SCLK period in order to detect it as a valid trigger by the ACM trigger logic.

- When the ACM is used in conjunction with the SPORT, the setup and hold timing requirements for the SPORT data signals with respect to ACLK are different from those requirements with respect to

internally-generated or externally-supplied SPORT clock. Consult the ADSP-BF60x Embedded Processor Data Sheet for information on these timing requirements.

When using Gated clock mode (`ACM_CTL.CLKMOD=1`), the interfaced serial mode should also be configured in Gated clock mode (`SPORT_CTL.GCLKEN=1`). In this case, it is required to satisfy some conditions in order to set-up the serial port in Gated clock mode. These conditions are:

- The serial port needs at least 7 serial clock cycles between enabling the SPORT and first frame sync. If this requirement is not met, the SPORT may drop the first data. (For subsequent data this requirement is not applicable).
- The frame sync should be in the inactive (de-asserted) state when the SPORT is enabled. Otherwise one extra cycle (in addition to the above mentioned) is needed before the frame sync can be applied. If this requirement is not met, the SPORT may drop the first data.

## ACM External Pin Timing

The ACM clock (ACLK) is derived internally from SCLK1 clock using the CKDIV divider specified in the ACM\_TC0 register. The other output signals such as ADC control pins (`ACM_A[4:0]`) and CS are driven on the rising edge of SCLK1 clock. As a result, these signals may not be synchronous to ACLK. The setup, hold, and other timing parameters of the ADC control signals, width of CS signal and the frequency of ACLK can be configured in the ACM timing configuration registers (`ACM_TCx`). The polarity of CS and ACLK can be configured in the ACM control register (`ACM_CTL`). The timing parameters of the ADC control pins (`ACM_A[4:0]`) cannot be individually specified.

The inactive period of CS ( $t_{CSIW}$  as shown in the following figure) is the sum of the three timing parameters – Setup Time ( $t_s$ ), Zero Time ( $t_z$ ) and the Hold Time ( $t_H$ ):

$$t_{CSIW} = t_s + t_z + t_H.$$

**Figure 27-4:** ACLK Timing Reference

Appropriate specification of values of these three parameters can yield the desired inactive period of CS.

In order to provide a predictable latency from the occurrence of an internal event to the assertion of an external ADC sampling event, the ADC controls and CS must be driven on the rising edge of SCLK. Therefore, the Setup Time ( $T_s$ ) of these signals is specified in terms of SCLK. However, the hold-time and zero-time are specified in terms of ACLK cycles.

To achieve accurate timing relationship between CS and ACLK (which is a normally a free running clock), the ACLK signal is re-aligned with the active edge of CS. This realignment of ACLK ensures that the setup time of the first active edge of ACLK, with respect to the active edge of CS, is at least 1ACLK cycle.

The figures in the following sections show various scenarios of ACLK re-alignment. All of these figures assume an ACLK:SCLK ratio of 1:4.

- Case 1—Chip Select Asserted during the High Phase of ACLK
- Case 2—Chip Select Asserted During the Low Phase of ACLK
- Case 3—Chip Select Asserted Right Before the Falling Edge of ACLK
- Case 4—Chip Select Asserted Right Before the Rising Edge of ACLK
- Case 5—ACLK Polarity Set to 1 (CLKPOL=1)

Notice that re-alignment of ACM clock causes suppression or extension of clock edges, leading to duty cycle variation. It is important to ensure that systems interfacing with the ACM can tolerate such duty cycle variation.

The figures show both the ACM-generated CS signal, which is output externally onto the appropriate ACM0FS pin, and the serial port receive frame sync (SPORT1\_xFS) signal, which is an internal signal that is routed to the frame sync input of the appropriate SPORT.

Please note that ACM clock polarity can be configured using the CLKPOL bit of ACM control register. After assertion of CS signal, the first edge of ACLK can be configured to be either rising edge or falling edge. Also, by default the clock is free running; it is possible to gate the ACM clock during inactive CS period using the CLKMOD bit of the same register.

## **Case 1—Chip Select Asserted During the High Phase of ACLK (CLKPOL=0)**

The following figure shows the realignment of ACLK when CS is asserted during the high phase of ACLK. The first edge of ACLK after the assertion of CS is the falling edge.

The two reference clock signals (RefACLK1 and RefACLK2) are shown to illustrate how the ACLK signal can be generated from a free running clock (RefACLK1) in order to meet the timing requirements between ACLK and CS. RefACLK2 is based on the free running clock RefACLK1, but is adjusted such that its period is immediately reset upon the assertion of CS. The resulting ACLK signal, shown in the figure, is such that the time from the active edge of CS to the falling edge of ACLK is constant at a period of 1ACLK cycle.

**Figure 27-5:** Chip Select Asserted During the High Phase of ACLK

### Case 2—Chip Select Asserted During the Low Phase of ACLK (CLKPOL=0)

When CS is asserted during the low phase of ACLK, as shown in the following figure, ACLK is immediately pulled high causing a duty cycle variation. In this case, similar to Case 1, the time from the active edge of CS to the falling edge of ACLK is 1ACLK period.

**Figure 27-6:** Chip Select Asserted During the Low Phase of ACLK

### Case 3—Chip Select Asserted Right Before the Falling Edge of ACLK (CLKPOL=1)

When CS is asserted right before the falling edge of ACLK, the falling edge of ACLK is suppressed, as shown in the figure. This ensures that the time from the active edge of CS to the falling edge of ACLK is constant at a period of 1ACLK cycle.

**Figure 27-7:** Chip Select Asserted Right Before the Falling Edge of ACLK

#### Case 4—Chip Select Asserted Right Before the Rising Edge of ACLK ( $CLKPOL=0$ )

When CS is asserted right before the rising edge of ACLK, the high phase of ACLK is extended, as shown in Figure. This extension ensures that the time from the active edge of CS to the falling edge of ACLK is constant at a period of 1 ACLK cycle.

**Figure 27-8:** Chip Select Asserted Right Before the Rising Edge of ACLK

#### Case 5—ACLK Polarity Set to 1 ( $CLKPOL=1$ )

When the ACLK polarity is set to 1 (bitCLKPOL is set to 1 in the ACM Control register), the first ACLK edge after the assertion of CS is the rising edge. The ACM ensures that the time from the active edge of CS to the rising edge of ACLK has a constant duration of 1 ACLK cycle. The figure shows an example diagram of the case where CLKPOL=1.

**Figure 27-9:** ACLK Polarity Set to 1

## ACM Architectural Concepts

The following sections provide information on the architecture of the ACM module.

### ACM Block Diagram

The ADC Control Module consists of two independent 32-bit ACM Timers, 16 Event Register pairs, 16 Event Comparators and a Timing Generation Unit.

ACM can accept four trigger inputs (internal as well as external signals); and on receiving a valid trigger on selected trigger input, the ACM timer/s start counting (based on the Mode of ACM). The trigger input can be independently selected for each timer.

Two sets of 8 event register pairs (total 16 event register pairs) determines the ADC controls for each ADC sampling, and also determines when the sampling happens. The Event register pair consists of: Event Control Register (ACM\_ERx) and the Event Time Register (ACM\_ETx). The Event Comparators Unit, compares the ACM Timer's count with Event Time of associated enabled events and, upon matching the count, signals appropriately to Timing Generation Unit. The Timing Generation Unit starts handling the events by driving the CS and ACM[4:0] signals accordingly.

The ACM Block diagram is shown below:

The following sections discusses about these blocks in detail.

## ACM Trigger Inputs

ACM can accept four trigger inputs, based on which ACM timers start running at **SCLK1** rate. ACM contains two 32-bit internal timers; each can be independently configured to use one of these trigger input. The two separate fields, **TRGSEL0** and **TRGSEL1**, of ACM Control register selects the trigger input for **ACMTIMER0** and **ACMTIMER1** respectively.

Therefore, ACM uses two trigger inputs when both ACM timers are enabled for different trigger inputs. However, it uses only one trigger if both ACM Timers are enabled for same trigger input or if single ACM Timer is enabled. The non-selected trigger inputs are 'don't care' for ACM. So, at most two and at least one selected trigger input should be active in the system for ACM to start its operation.

The four possible trigger inputs are briefly described below:

- ACMTriggerinput0 (ACM\_T0) – PE8:

Trigger input- 0 is sourced from PE8 pin of the PORTE (sometimes also referred as GPIO[72]). When ACM is enabled, input tap on PE8 pin is enabled; so, ACM trigger input can be from any source (internal or external) depending on PE8 pin configuration.

When PE8 pin is configured in GPIO mode (FER=0), the source of GPIO signal may be either internal or external depending on the GPIO direction configured in PORTE\_DIR register. When PE8 pin is configured in function mode (FER=1), the trigger- 0 input is sourced in from peripheral signals based on PORTE\_MUX register setting for PE8 pin. For example the ACM can source this trigger input from PWM0\_SYNC signal (internally generated by PWM unit or externally provided), if MUX bits for PE8 pin are set to b#00. Whereas, if MUX bits for PE8 are configured to b#01, trigger input is sourced from PPIO\_FS1 signal (internally generated by EPPIO unit or externally-generated).

So, FER and MUX bits for PE8 pin must be programmed appropriately considering the source of trigger input. Enabling input tap ensures that ACM operation would not interfere with module driving the PE8 pin.

- ACMTriggerinput1 (ACM\_T1) – PG5:

Trigger input- 1 is sourced from PG5 pin of the PORTG (sometimes also referred as GPIO[101]). When ACM is enabled, input tap on PG5 pin is enabled; so, ACM trigger input can be from any source (internal or external) depending on PG5 pin configuration.

When PG5 pin is configured in GPIO mode (FER=0), the source of GPIO signal may be either internal or external depending on the GPIO direction configured in PORTG\_DIR register. When PG5 pin is configured in function mode (FER=1), the trigger- 1 input can be sourced in from peripheral signals based on PORTG\_MUX register setting for PG5 pin. E.g. ACM can source this trigger input from PWM1\_SYNC signal (internally generated by PWM unit or externally generated), when MUX bits for PG5 pin are set to b#10.

So, FER and MUX bits for PG5 pin must be programmed appropriately considering the source of trigger input. Enabling input tap ensures that ACM operation would not interfere with module driving the PG5 pin.

- ACMTriggerinput2 (ACM\_T2) – ACMSlaveTriggerID33:

The Trigger Routing Unit of processor provides system-level sequence control without core intervention. When this trigger input mode is selected, ACM acts as Trigger Slave and accepts trigger through Trigger Slave ID- 33. The 'Slave Select' (SSR) field of TRU\_SSR33 register should be configured to receive triggers from a specific trigger Master. In this way, ACM\_T2 trigger input can accept triggers asserted by that particular trigger Master or through software by writing ID of that trigger Master to one of the four fields in the TRU\_MTR register. The trigger response from selected master is internally routed to ACM trigger input. This way, ACM slave trigger ID- 33 is capable of receiving any one of the 86 internal triggers available.

- ACMTriggerinput3 (ACM\_T3) – A CMSlaveTriggerID34:

Similar to ACM\_T2 input, ACMTriggerInput3 (ACM\_T3) is internally provided by Trigger Routing Unit of the processor. When this trigger input mode is selected, ACM acts as Trigger Slave and accepts trigger through Trigger Slave ID- 34. The 'Slave Select' (SSR) field of TRU\_SSR34 register should be configured to receive triggers from a specific trigger Master. In this way, ACM slave trigger ID 34 can accept triggers asserted by that particular trigger Master or through software by writing ID of that trigger Master to one of the four fields in the TRU\_MTR register. The trigger response from selected master is internally routed to ACM trigger input. This way, ACM slave trigger ID 34 is capable of receiving any one of the 86 internal triggers available.

Refer Trigger Routing Unit chapter for more details about Trigger slaves and Trigger masters.

For all trigger input signals, the active edge of the trigger is programmable in the ACM Control register as either rising edge or falling edge trigger.

The following figure shows the detailed ACM trigger generation logic.

**Figure 27-10:** Detailed ACM Trigger Generation Logic

When trigger sources external to the processor (e.g. ACM\_T[1:0]) are used for triggering the ACM Timers, the minimum pulse width for such trigger sources needs to be greater than one SCLK1 period.

**NOTE:** A latency of no more than four SCLK1 cycles exists between external trigger and ACM Timer starts counting. Please refer to [ACM Event Handling Latency](#) section for further details.

## ACM Timers

The ACM module has two independent 32-bit timers (ACMTMR0 and ACMTMR1) which start counting at system clock (SCLK1) rate upon detecting valid trigger on selected trigger input. The timers can be independently enabled using the timer enable bits (ACMTMR0EN, ACMTMR1EN) in the ACM Control register; and

can be independently configured for one of the four trigger inputs with configurable polarity of the signal. At least one ACM timer should be enabled for proper ACM operation.

By default, each ACM timer has 8 event associated with it. If both timers are enabled, the Event[7:0] are associated with ACMTMR0; while the Event[15:8] are associated with ACMTMR1. However, if only one timer is enabled, all of the event registers are associated with that particular timer. For example, if only ACMTMR1 is enabled, (if ACMTMR0EN=0 and ACMTMR1EN=1), all 16 events, Event[15:0], will be handled by ACMTMR1.

These timers start counting when a trigger input occurs that is selected for that particular timer. The timer only stops counting under one of the following conditions:

1. A timer rollover occurs.
2. All the events associated with the trigger have completed.

Note that a timer rollover can never happen, unless the Event Time Register of an event is programmed at some point after the trigger occurs; this is a practice that is contrary to ACM programming guidelines.

In the second case, the exact time at which the Timer stops counting depends on the FIFO state when the last event occurred internally.

If a trigger occurs while the timer is counting, the time resets and starts counting again. In this case, some of the events may miss resulting in flagging appropriate status bit and optionally an Event Missed interrupt.

When an ACM timer is disabled or the ACM itself is disabled, the timer resets to zero.

## **Event Register Pairs**

An Event, for the ACM, is a point in time where ADC sampling has to happen on a particular channel of the ADC with the specified control settings of the ADC.

ACM can handle total 16 events which are grouped into two sets of 8 events. As explained in ACM Timer sections, either 8 events can be assigned to each of the timers (if both timers are enabled) or all 16 events can be assigned to one particular timer (if only one timer is enabled).

All events can be independently configured and enabled. The enabled events determine the ADC controls and timing for each ADC sampling interval. Each event consist a register pair comprising an event control register (ACM\_ERx) and an event time register (ACM\_ETx). The ACM\_ERx register enables a particular event and determines settings for the ADC control lines (ACM\_A[4:0]) for that particular ADC conversion. The ACM\_ETx register determines the time offset from the corresponding ACM timer trigger input to the start of that particular event (i.e. when the event has to occur w.r.t. trigger input). This time offset should be specified in terms of system clock 1 of the processor.

At least one event, associated with enabled ACM Timer, should be enabled for ACM to execute ADC sampling.

## Event Comparators Unit

The Event Comparator block consists of 16 event time comparators which determine when an enabled event should happen. After detecting valid trigger on selected trigger input, ACM timer starts running at system clock 1 rate. The comparators compare the ACM timer count with the event time specified in the `ACM_ETx` register of the enabled event. If the time value matches, the comparators indicate an active event signal to the timing generation unit.

If an event happens when another event is ongoing, the occurred event is stored in the pending event FIFO of Timing Generation Unit. If more than one event associated with a ACM Timer are active during the same `SCLK` cycle, only the highest priority event is processed, and all other events are missed (even if there was space in the pending event FIFO). However, if both Timers are enabled and if multiple events associated with both ACM Timers are active at the same `SCLK` cycle, then two events, one highest priority active event per each timer, are signaled.

The priority of events is fixed; event with lowest event ID has higher priority compared other events.

When both ACM Timers are enabled, Event0 has the highest priority and Event7 has the lowest priority in the `Event[0:7]` group associated with `ACMTIMER0`. Similarly Event8 has the highest priority and Event15 has the lowest priority in the `Event[8:15]` group associated with `ACMTIMER1`. So if Event1 and Event5 occur simultaneously, then Event5 is missed, even if there is space in the pending FIFO. But between the `Event[0:7]` and `Event[8:15]` group, simultaneous events can be written into the FIFO. For example, if Event0 and Event9 occur together, then both are written into the FIFO, `Event[0:7]` group has higher priority, so the order of Events in the FIFO is Event0 first and then Event9. If Event1, Event5, Event9, Event15 happened together, then Event5, and Event15 are missed and Event1 and Event9 are put into the FIFO (Event1 first followed by Event9). When events that are triggered by both timers occur simultaneously, the event triggered by `ACMTMR0` is given higher priority.

When only single ACM Timer is enabled, then all 16 events, `Event[0:15]`, are assigned to that timer. So, Event0 has highest priority; while Event15 has lowest priority. So, in this case, if Event1, Event5, Event9, Event15 happened together, then only Event1 will be placed in forwarded, while Event5, Event9 and Event15 will be missed, even if there is space in the pending FIFO.

If an event is missed, the `EMISS` bit in the ACM Status register (`ACM_STAT`) and the corresponding bit in the ACM Event Missed Status register (`ACM_MEVSTAT`) are set.

## Timing Generation Unit

After event signaling from event comparators, the timing generation unit initiates an ADC sampling interval as per settings of that particular event. It generates ADC control signals based on the Event parameter field of the `ACM_ERx` register setting. The timings of output signals (`ACLK`, `CS`, `A[4:0]`) are determined by the ACM Timing registers (`ACM_TCx`) which contains the fields like Set-up time, Hold time and Zero time for these signals in addition to ACM clock divider.

The Pending FIFO is part of Timing Generation Unit. If an event happens when ACM is busy with another event, the occurred event is stored in the pending event FIFO. This pending event is serviced (for example, the ACM starts an ADC conversion for the event that occurred), after completion of ongoing event.

The pending event FIFO has a depth of 4, so it can hold up to four pending events. If an event occurs when the pending event FIFO is full, that event is missed. If an event is missed, the `EMISS` bit is set in the `ACM_STAT` register and the corresponding bit in the `ACM_MEVSTAT` register also is set.

On disabling the ACM, all the pending entries in the pending FIFO are flushed.

## Status Flags and Interrupts

The ACM provides a read-only Status register (`ACM_STAT`) to check the module activities such as which event is currently being serviced, whether any event has been missed events or all the events has been serviced for the current trigger.

In addition to this Status register, ACM also provides two general-purpose status registers, ACM Event Completion Status register (`ACM_EVSTAT`) and ACM Missed Event Status register (`ACM_MEVSTAT`). The `ACM_EVSTAT` register specifies servicing of which enabled events has completed for a particular trigger cycle; while `ACM_MEVSTAT` register specifies which enabled event has been missed for that particular trigger cycle. This information is provided for all the 16 events via individual bits.

Based on these status bits, ACM can generate two interrupts, event completed or event missed, for each event. These interrupts can be selectively enabled for particular ACM events via ACM Completed Event Interrupt Mask Register (`ACM_EVMSK`) and ACM Missed Event Interrupt Mask Register (`ACM_MEVMSK`) registers.

The Event Completion interrupt is generated only after the entire event completes externally (for example, when `CS` signal goes inactive, and Hold Time (`TH`), Zero Time (`TZ`) periods are completed for that particular event). The `ACM_EVSTAT` register provides the status of each event indicating which event has caused the interrupt. It is also possible to generate this interrupt when all the events associated with an ACM Timer are completed for an ACM trigger cycle. This interrupt can be cleared by writing to the relevant `W1C` (write 1 to clear) bit in `ACM_EVSTAT` register.

The Event Missed Interrupt is generated when an enabled event is missed for a trigger cycle and the corresponding mask bit of `ACM_MEVMSK` register is set. The event might be missed in Event comparator unit if more than one event, related to same Timer, are active during the same `SCLK1` cycle; or it can be missed in Timing Generation Unit if an event occur when event pending FIFO is full. The `ACM_MEVSTAT` register provides the status of each missed event indicating which event miss caused the interrupt. This interrupt can be cleared by writing the relevant `W1C` bit in the `ACM_MEVSTAT` register.

**NOTE:** A Status bit set either in `ACM_EVSTAT` or `ACM_MEVSTAT` registers triggers an interrupt only if the corresponding bit in the `ACM_EVMSK` or `ACM_MEVMSK` registers is enabled.

In addition to Event Completion interrupt (upon completion of particular event or all events), ACM can also provide an trigger output to Trigger Routing Unit of the processor. This trigger output can be used by Trigger slaves for their operations without requiring core intervention.

Event Order Registers

For debugging purpose, BF60x ACM hardware includes 16 Event Order registers-one per each event-which indicates the order in which the events were completed externally.

These registers are denoted as ACM\_EVORDx, where x stands for event ID, 0 to 15. The 8-bit EVT\_ORDER field of this register indicates in which order the ADC data has been captured corresponding to the event. This field accumulates the order count every trigger cycle, unless it is cleared in the software. At each trigger cycle, the values of the register will be updated, so it must be read at the end of the each trigger cycle (as it will write the new order value of the event in the next trigger cycle). Thus, the 8-bit field can store the order of 256 data captures at a stretch, after which it will start the order count from zero again.

All the event registers can be reset in software by setting ORDR\_RST bit of the ACM control register. When set, it clears all the Event Order Register value to zero. This bit auto-clears to 0 after all ACM\_EVORDx registers are cleared. These registers can also be cleared automatically by selected trigger input of ACM Timers, if AOREN bit is set. The OTSEL bit of the ACM Control register determines which trigger input to select for this auto-clearing.

The Event Order functionality is explained below with an example where ACM has only three events enabled (let it be Event1, Event7 and Event13). Following figure shows how the Order register value of these events will be at different stages.

Figure 27-11:

ACM Register List

Table 27-1: ACM Module Registers

| Name    | Description          |
|---------|----------------------|
| ACM_CTL | ACM Control Register |

**Table 27-1:** ACM Module Registers (Continued)

| Name        | Description                                 |
|-------------|---------------------------------------------|
| ACM_TC0     | ACM Timing Configuration 0 Register         |
| ACM_TC1     | ACM Timing Configuration 1 Register         |
| ACM_STAT    | ACM Status Register                         |
| ACM_EVSTAT  | ACM Event Status Register                   |
| ACM_EVMSK   | ACM Completed Event Interrupt Mask Register |
| ACM_MEVSTAT | ACM Missed Event Status Register            |
| ACM_MEVMSK  | ACM Missed Event Interrupt Mask Register    |
| ACM_EVCTLn  | ACM Eventn Control Register                 |
| ACM_EVTIMEn | ACM Eventn Time Register                    |
| ACM_EVORDn  | ACM Eventn Order Register                   |
| ACM_TMR0    | ACM Timer 0 Register                        |
| ACM_TMR1    | ACM Timer 1 Register                        |

## ADSP-BF60x ACM Interrupt List

**Table 27-2:** ADSP-BF60x ACM Interrupt List

| Description         | ID | DMA Channel | Sensitivity |
|---------------------|----|-------------|-------------|
| ACM0 Event Miss     | 38 |             | LEVEL       |
| ACM0 Event Complete | 39 |             | LEVEL       |

## ACM Programming Concepts

Since ACM module is being used with the SPORT, PWM, GPTIMER and GPIO; the programming must comply with the following guidelines for reliable operation of the ACM.

- ACM is control module and provides clock and chip select and control signals with required timing. But for capturing the data from ADC, one of the half of SPORT1 is used.
- The ACM should be enabled before enabling the SPORT. But SPORT can be configured before enabling ACM. SPORT should be configured in slave mode [external clock (ICLK=0), external frame sync(IFS=0)] as receiver.

The timings of external ADC decide the settings of LFS, LAFS, CKRE bits of SPORT Control register. Generally SPORT is configured in DSP serial mode to receive the ADC samples, but other operating mode (such as multichannel) may be possible.

If ACM is supposed to be programmed to gated clock mode (CLKMOD=1), the serial port should also be set in gated clock mode(GCLKEN=1).

- DMA mode of SPORT operation is preferred, as it saves the processor MIPS when receiving chunk of data. However, receiving ADC sample in core mode is also possible. So, when using DMA mode, DMA registers of selected SPORT should be configured appropriately; and DMA must be enabled before enabling SPORT. When using both primary and secondary channels of SPORT to receive data from two ADC channels, the 2D feature of DMA can be effectively used to de-interleave the data from two channels. When using Core mode of SPORT operation, core handler should be registered to handle the data read requests from SPORT receiver.
- In addition to SPORT register settings, the PORT registers should also be set properly to enable SPORT Data pins, ACM clock, CS and Control pins. When using either of the ACM\_T[1:0] trigger inputs for ACM Timers, FER and MUX bits of corresponding pins (PE8 or PG5) must be configured properly according to source of trigger input.
- When using ACM\_T[2:3] trigger inputs for ACM timers, the Trigger Routing Unit can be configured and enabled at this step. The corresponding Slave Trigger ID should be programmed properly using Slave Select Register to select the required master trigger. When using these trigger inputs, the Slave select register must not be configured when ACM is enabled, as default value of this register zero and Master Trigger ID-0 is system reserved.
- Before enabling the ACM (by setting the ACMEN bit), all the control bits of ACM Control register should be programmed properly. These control bits includes ACM trigger selects (TRGSELx), trigger input polarities (TRGPOLx), CS signal polarity (CSPOL), ACM clock polarity (CLKPOL), ACM clock mode (CLKMOD) and Serial port unit selection, Event order register settings.
- Configure the ACM Timing Control registers to define the ACM clock frequency and setup, hold & zero time of ACM control signals.
- The Timer Enabled (TMRENx) bits, however, should be programmed together only after ACM is enabled but once the bits are programmed it should not be changed later. Modifying these enable bits in the ACM Control register is not recommended while the ACM is in operation. Doing so can cause events

to change dependency from one timer to the other and can cause the values in the ACM status registers (ACM\_EVSTAT and ACM\_STAT) to be inaccurate. This means that if both timers are required for use, then enable them together after ACM is being enabled. If one timer is already enabled, then disable ACM, re-enable ACM and then program both timer enable bits together. Similarly when both timers are running, they should be disabled together.

- Once configuration peripherals are done, ACM should be enabled first and then SPORT module (SPORT DMA should be enabled before enabling SPORT, can be in previous steps also). Ideally trigger should not active when enabling the ACM.
- After enabling ACM, the event register pairs (Event Control and Event Time registers) should be configured and enabled to create required events.
- It should be noted that ACLK is an external clock relative to the SPORT peripheral. Therefore, any SPORT requirements around a minimum number of stable external clock cycles before assertion of the first SPORT frame sync need to be observed. The SPORT requires a minimum of 3 clock cycles before it is able to recognize a frame sync. When SPORT is configured in gated clock mode, this requirement becomes a minimum of 7 SPORT clock cycles. Therefore the required number of ACLK cycles should elapse before first assertion of CS. This can be guaranteed by any of the following methods:
  - Ensuring that ACM triggers are generated at least 3ACLK cycles after the ACM is enabled.
  - Ensuring that the event time value (ACM\_ETx) of the first active event is such that 3ACLK cycles would elapse before the event is processed.
- When the minimum number of ACLK cycles before the assertion of CS is not observed, the SPORT may miss the data of the first ADC sampling event. There can be a software workaround for fulfilling this requirement. Program the ACM\_TCO register (CKDIV value) after enabling the SPORT (subsequently after enabling ACM) but before the trigger is applied. Since the default value of CLKDIV is 1, the ACLK frequency is higher. Therefore the SPORT may receive the required clock cycles within short period of time (before the Frame Sync arrives).
- When using ACM\_T[2:3] trigger inputs, the master can be enabled at last (if it is configured only to provide triggers to ACM) to generate the triggers.
- While disabling the ACM system, the SPORT should be disabled first, then DMA and finally the ACM should be disabled.

## Emulation Mode Use Case

This section describes the usage modes of the ACM by illustrating how to implement various sequencing ADC sampling modes.

### Single-Shot Sequencing Mode Emulation

In single-shot sequencing mode, all enabled events are sequentially issued one after the other on the occurrence of an ACM trigger. The sequence of events is fixed, starting with Event0 and ending with Event15.

The following figure shows an example of single-shot sequencing mode where only Event0 and Event1 are enabled. ETIME0 is the value written into the ACM\_ET0 register, and ACMTMR0 is enabled in this mode. To emulate this mode of operation using the ACM.

**Figure 27-12:** Single Shot Sequencing

- Configure the appropriate trigger source for initiating ACM activity. Please refer to “Interface Overview” for information on signals that can trigger the ACM counters.
- Enable only one ACM timer (ACMTMR0)
- Enable events and program the event time values as: Event0 time = X, Event1 time = X + Y, Event2 time = X + 2Y where:

$X = \text{ETIME0}$ , the initial time offset from trigger (if needed)

$Y = t_H + t_{CSW} + t_S + t_Z$ , where  $t_H$  is the hold time,  $t_Z$  is the zero t time, and  $t_S$  is the setup time for ACM Control lines as specified in ACM Timing Registers. For more information, refer "ACM External Pin Timing" section.

**NOTE:** Y has to be slightly less than the above value to ensure that the next event occurs before the first event completes, so that the next event is in the pending FIFO and enables the transitions between events without a break.

## Continuous Sequencing Mode Emulation

Continuous sequencing mode is similar to single-shot sequencing mode, except in continuous sequencing the event sequencing is continuously repeated. As in single-shot mode, the time offset is programmable in continuous mode. The trigger in continuous mode is relevant only for the first time. Therefore, any subsequent triggers after the first active edge of the trigger are neglected.

The following figure shows an example of continuous sequencing mode with only two events – Event0, Event1 enabled. To emulate continuous sequencing mode using ACM:

**Figure 27-13:** Continuous Sequencing

- Enable only one ACM Timer (say ACMTIMER0). Select Timer trigger input as from TRU of processor i.e. either of the ACM\_T[3:2].

If ACM\_T2 is selected, program ACM Slave Trigger ID-33 to select ACM Event Completion (whose master Trigger ID is 19) as trigger input. If ACM\_T3 is selected as trigger input, configure ACM Slave Trigger ID-34.

- Configure rest of the settings required by programming ACM Control and Timing Registers.
- Enable ACM Events with required ACM Control lines settings.

Program the Event time registers as: Event0 time = X, Event1 time = X + Y, Event 2 time = X + 2Y where:

X and Y values, in terms of SCLK1, are as described in the single-shot case (Y can be slightly less than  $t_H + t_{CSW} + t_S + t_Z$  to avoid any break between Events)

- Configure and enable System event controller.

Also configure, map and enable the ACM Event Completion interrupt which will interrupt upon completion of all enabled ACM Events for the current trigger. That means, set only ECOMP0 (or ECOMP1, if using ACMTIMER1) bit of ACM Event Interrupt Mask (ACM\_EVMSK) register.

- Enable ACM, SPORT and SPORT DMA as per the guidelines given in "Programming Concepts" section.
- Since we have configured ACM Trigger input as ACM Event Completion trigger output, the first trigger is necessary to start the ACM operation. We can provide this dummy trigger by writing Master Trigger ID into Master Trigger register (TRU0\_MTR).

So, write ACM Event Completion Trigger ID (19) into TRU0\_MTR register. This will trigger the ACM Timers and ACM will start handling the events.

- After completing all events, ACM will provide Event Completion Trigger and corresponding interrupt will be generated. The ACM Trigger output will be provided to ACM Timers which will reset it's counter and start running from zero, which will cause ACM to re-handle all the enabled ACM events. And this sequence continues.

However, in order to provide the Trigger outputs properly, the interrupt latch must be cleared in the ISR by clearing `ECOMP0S` (or `ECOMP1S`, if using `ACMTIMER1`) bit of the ACM Event Completion Status register (`ACM_EVSTAT`).

## ACM Register Descriptions

ACM (ACM) contains the following registers.

**Table 27-3:** ACM Module Registers

| Name                     | Description                                 |
|--------------------------|---------------------------------------------|
| <code>ACM_CTL</code>     | ACM Control Register                        |
| <code>ACM_TC0</code>     | ACM Timing Configuration 0 Register         |
| <code>ACM_TC1</code>     | ACM Timing Configuration 1 Register         |
| <code>ACM_STAT</code>    | ACM Status Register                         |
| <code>ACM_EVSTAT</code>  | ACM Event Status Register                   |
| <code>ACM_EVMSK</code>   | ACM Completed Event Interrupt Mask Register |
| <code>ACM_MEVSTAT</code> | ACM Missed Event Status Register            |
| <code>ACM_MEVMSK</code>  | ACM Missed Event Interrupt Mask Register    |
| <code>ACM_EVCTLn</code>  | ACM Eventn Control Register                 |
| <code>ACM_EVTIMEn</code> | ACM Eventn Time Register                    |
| <code>ACM_EVORDn</code>  | ACM Eventn Order Register                   |
| <code>ACM_TMR0</code>    | ACM Timer 0 Register                        |
| <code>ACM_TMR1</code>    | ACM Timer 1 Register                        |

## ACM Control Register

### ACM\_CTL: ACM Control Register - R/W

Reset = 0x0000 0000

**Figure 27-14:** ACM\_CTL Register Diagram

**Table 27-4:** ACM\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                         |
|---------|----------|---------------------------------------------------------------------------------|
| 15      | EPS      | External Peripheral Select.                                                     |
|         |          | 0 SPORT2 interfaces to ACM                                                      |
|         |          | 1 SPORT1_B interfaces to ACM                                                    |
| 14      | OTSEL    | Trigger Select for Order Register Reset.<br>Applicable only if AOREN bit is set |
|         |          | 0 TMR0 trigger will reset the order registers                                   |
|         |          | 1 TMR1 trigger will reset the order registers                                   |

**Table 27-4:** ACM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                   |                                                        |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| 13      | AOREN    | Automatic Order Reset Enable.<br>(OTSEL selects which Trigger)                                                                                            |                                                        |
|         |          | 0                                                                                                                                                         | Automatic Order Reset with Trigger is disabled         |
|         |          | 1                                                                                                                                                         | Automatic Order Reset with Trigger is enabled          |
| 12      | ORST     | Order Register Reset Bit.<br>If set it clears all the Event Order Register value to 0. This bit auto-clears to 0 after Event Order registers are cleared. |                                                        |
| 11      | CLKMOD   | ADC Clock Mode.                                                                                                                                           |                                                        |
|         |          | 0                                                                                                                                                         | ACM generates continuous ACLK                          |
|         |          | 1                                                                                                                                                         | ACLK is gated when CS is inactive                      |
| 10      | CLKPOL   | ADC_CLK Polarity.                                                                                                                                         |                                                        |
|         |          | 0                                                                                                                                                         | Falling edge of ADC_CLK comes after ADC_CS goes active |
|         |          | 1                                                                                                                                                         | Rising edge of ADC_CLK comes after ADC_CS goes active  |
| 9       | CSPOL    | CS Polarity.                                                                                                                                              |                                                        |
|         |          | 0                                                                                                                                                         | Active Low CS                                          |
|         |          | 1                                                                                                                                                         | Active High CS                                         |
| 8       | TRGPOL1  | Trigger Polarity for Timer1 Triggers.                                                                                                                     |                                                        |

## 28 Link Port (LP)

Link ports allow the processor to connect to other processors or peripheral link ports using a simple communication protocol for high-speed parallel data transfer. This peripheral allows a variety of I/O peripheral interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes.

The ADSP-BF60x processor has four link ports and each supports 8-bit wide data transfers. The link port pins are multiplexed in the GPIO ports as follows.

- Link port 0 and 1 signals are multiplexed in GPIO ports A and B.
- Link port 2 and 3 signals are multiplexed in GPIO ports E and F.

Each of these identical modules can operate independently and simultaneously, allowing glueless high-speed connectivity of up to four external processors in BF60x.

### LP Features

All link ports are identical in their design and have the following common features.

- Bidirectional ports with eight data lines, an acknowledge line, and a clock line.
- Provide high-speed, point-to-point data transfers to other processors, allowing different types of interconnections between multiple DSPs
- Pack data into 32-bit words. This data can be directly read by the processor or transferred via DMA to or from on-chip memory.
- Support for data buffering through 2-deep FIFO for transmit and 4-deep FIFO for receive.
- Programmable clock and acknowledge based handshake mechanism for efficient communication.
- Dedicated DMA channel.

### LP Functional Description

This section provides a description of the link port, including a list of its registers and a functional block diagram.

## LP Register List

The LP are 8-bit wide ports, which can connect to another processor or peripheral LP. These ports allow a variety of interconnection schemes to I/O peripheral devices as well as co-processing and multiprocessing schemes. A set of registers govern LP operations. For more information on LP functionality, see the LP register descriptions.

**Table 28-1:** LP Module Registers

| Name          | Description                   |
|---------------|-------------------------------|
| LP_CTL        | Control Register              |
| LP_STAT       | Status Register               |
| LP_DIV        | Clock Divider Value           |
| LP_TX         | Transmit Buffer               |
| LP_RX         | Receive Buffer                |
| LP_TXIN_SHDW  | Shadow Input Transmit Buffer  |
| LP_TXOUT_SHDW | Shadow Output Transmit Buffer |

## ADSP-BF60x LP Interrupt List

**Table 28-2:** ADSP-BF60x LP Interrupt List

## LP Block Diagram

The block diagram of a link port is shown in the following figure.

Figure 28-1: Link Port Block Diagram

## External Connections

A link port has eight data lines (LDAT7-0), a clock line (LCLK), and an acknowledge line (LACK). A link port can act as either (one at a time) a transmitter or a receiver.

X DENOTES THE LINK PORT NUMBER, 0-4

Figure 28-2: Link Port Pin Connections

External pull downs should be used for the LCLK and LACK pins so that the transmitter and receiver can be enabled, irrespective of the state of the other.

## Internal Blocks

As shown in the [Link Port Pin Connections](#) figure, the link ports have independent modules for transmit and receive. If enabled as transmitter, the link port uses a 2 deep 32-bit FIFO. If enabled as a receiver, the port uses a 4 deep 32-bit FIFO. These FIFOs can be accessed by the core MMR access bus as well as through the distributed DMA engines (DDE) through the system cross bar (SCB) interface. The `LTRAN` bit in the link port control register determines whether the module is enabled for transmit or receive operation.

## LP Architectural Concepts

This section describes link port architectural concepts, including link port protocol, buffers, intercommunication, clocking, and multi-processor connectivity.

### Link Port Protocol

A link port transmitted word consists of 4 bytes. The transmitter asserts the Link port clock (`LCLK`) with each byte of data. The falling edge of `LCLK` driven by the transmitter is used by the receiver to latch the byte. When the receiver is ready to accept another word in the receive buffer it asserts the acknowledge signal, `LACK`. The transmitter samples `LACK` driven by the receiver at the beginning of each word transmission. If `LACK` is de-asserted at that time, the transmitter does not transmit the next word. The transmitter leaves `LCLK` high and continues to drive the first byte of the next word until `LACK` is asserted. When this assertion occurs, `LCLK` is driven low by the transmitter and the transmission of the next word starts. If the transmit buffer is empty, `LCLK` remains low until the buffer is refilled, regardless of the state of `LACK`.

The `LACK` signal may de-assert when it anticipates that the buffer may fill. The `LACK` signal is reasserted by the receiver as soon as the internal DMA grant signal has occurred or the core reads the receive buffer. Either of these actions frees a buffer location.

**NOTE:** The `LACK` signal inhibits transmission of the next word and not of the current byte.

Link port acknowledge (`LACK`) provides a handshake between the receiver and transmitter in the following configurations.

- When configured as a transmitter, the port drives both the data and the clock while `LACK` is three-stated. In this mode `LCLK` is always synchronous with `SCLK`.
- When configured as a receiver, the link port drives the acknowledge signal and the data and clock lines are three-stated. In this case, external `LCLK` can either be synchronous or asynchronous with `SCLK`.
- When the link port is disabled, data, clock and acknowledge signals are three-stated.

**Figure 28-3:** Link Port Communication and Handshake Waveform

The following list describes the stages shown in the *Link Port Communication and Handshake Waveform* figure.

1. LCLK stays high at byte 0 if LACK is sampled low on the previous LCLK rising edge. LCLK high indicates a stall.
2. The LACK signal may de-assert after byte 0.
3. The LACK signal reasserts as soon as the link buffer is not full (depending on RX FIFO conditions).
4. The transmitter samples LACK to determine whether to transmit the next word.
5. The receiver accepts the remaining word even if LACK is de-asserted. The transmitter does not send the following word.
6. Transmission of data for next word is held until LACK is asserted.

The acknowledge signal (LACK) is sampled by the transmitter and if it is high, the transmitter gives out the falling edges of LCLK for data sampling. The LACK signal is first sampled at the rising edge of SCLK, is further synchronized by one more SCLK stage and then this synchronized signal is given to the subsequent logic. The LCLK falling edge is aligned with SCLK falling edge in a 1:1 clock ratio mode and with the SCLK rising edge for the rest of the clock ratios. The following figures explain how the synchronization is maintained between the LACK and LCLK signals.

**Figure 28-4:** LACK synchronization for SCLK:LCLK=1:1 (synchronizing time is guaranteed to be 1.5 SCLK cycles).

**Figure 28-5:** LACK synchronization for SCLK: LCLK=1:2, 1:4 and Up (synchronizing time is guaranteed to be 2 SCLK cycles).

The frequency of the link port clock (LCLK) is determined by the value programmed in the CLKDIV register at the transmitter. However, the signal appearing on the LCLK pin is also dependent on the status of the LACK pin driven by the receiver. The below figure explains this relationship.

**Figure 28-6:** Relationship Between Internal Link Port Clock and Link Port Clock at the Pins

## Link Port Buffers

When a link port is configured as transmitter, a 2-deep FIFO buffer is used. A shift register unpacks the single 32-bit word to four 8-bit data bytes. As the FIFO gets space for more data, a new DMA request is made. The core can access FIFO through the LP\_TX register. If the FIFO becomes empty, the LCLK signal is de-asserted. Three writes (2 stage FIFO and 1 Shift Register) can occur to the transmit buffer by the core or DMA before it signals a full condition. The status of the FIFO is reflected by the FFST field in the LPSTAT register. Shift Register full/empty condition is not provided to the user. However, the user may poll the LPBS bit in the LPSTAT to know if link port is driving data from Shift Register to the pins or not. LPBS is also set when receiver has held off transmission by driving LACK low.

**NOTE:** When the 2-deep FIFO and the output shift register overflows, any further write in to the link port buffer shall overwrite the input stage of the FIFO.

Transmit FIFO can also be read out by the core via data register LP\_TX.

If the Transmitter is disabled while performing writes to the transmit FIFO, a FIFO full condition will be signalled after just 2 writes.

Shadow registers have been provided for the transmit buffer registers. Using these shadow registers, both stages of the 2-deep FIFO may be read without updating the status registers. The LP\_TXIN\_SHDW register corresponds to the input stage of the FIFO and the LP\_TXOUT\_SHDW register corresponds to the output stage of the FIFO.

**Figure 28-7:** Transmit FIFO path

When a link port is configured as receiver, data is transferred to the core or DMA from the full 4-deep receive FIFO. An internal packing register performs the packing of data to 32 bits. Four reads can occur from the receive buffer by the core or DMA before it signals an empty condition. Status of the 4-deep read buffer FIFO is reflected by the `FFST` bits in the `LPSTAT` register. The core can access this FIFO through the `LP_TX` register.

**NOTE:** When receive FIFO overflows with Overflow bit in Status Register set, any further data from the transmitter shall be lost and only the data retained in the receive FIFO can be retrieved further.

The `LACK` output signal is driven low by the receiver once the first byte of data for the last but one empty slot (in the 4-deep FIFO) is received. This is to prevent data loss due to the transmitter starting transmission of the next word before the `LACK` signal reaches the transmitter (due to the larger delay in synchronization). This guarantees that even after allowing for the extra synchronization cycle in the transmitter and receiver, there is no overflow in the receive FIFO. *LACK Generation Based on Receive FIFO Status* (link port receive and transmit buffers) below shows how FIFO slots influence the acknowledge signal generation. The greyed section indicates the received data and the white section indicates the empty locations.

**Figure 28-8:** LACK Generation Based on Receive FIFO Status

**NOTE:** A 4-deep receive FIFO can be utilized only under a worst case scenario, and in all other cases, the FIFO must be thought of having only 3-deep stage.

Link port has memory mapped buffers for both receiver and transmit cases. Since these buffers are memory mapped, a JTAG based emulator (such as with ADI Cross Core Embedded Studio) may read the FIFO and thus can cause unexpected problems in data transfer. This can only happen during an emulation event (typically hitting a breakpoint or single-stepping), when emulator issues core reads via JTAG. CCES can block reading these FIFO buffers. For more information, please consult the CCES Help.

## Handshake for LP enable process

In a link port based system, the transmitter and the receiver may be enabled at different times. External pull downs should be used for LCLK and LACK.

If the receiver is enabled before the transmitter, LCLK (of the transmitter) is held low by the external pull down and the receiver is held off. Receiver can wait for a rising edge on the LCLK line to assert its Receive Service Request interrupt. This rising edge occurs only when transmitter starts driving the first data on to the bus, after it is enabled by the application.

If the transmitter is enabled before the receiver, LACK (of the receiver) is held low by the external pull down and transmission is held off, as shown in the below figure. Transmitter can wait for a rising edge on the LACK line to assert its Transmit Service Request interrupt. This rising edge is asserted as soon as receiver is enabled with LACK driven high subsequently by hardware.

**Figure 28-9:** Enabling Transmitter before Receiver

**NOTE:** Service Request Interrupts / Status are asserted only when the link port (receiver or transmitter) is disabled.

## Clocking

Link port clock (LCLK) is derived out of the internal system clock (SCLK0). The link port clock to system clock ratio can be programmed using the DIV field of link port divider register (LPDIV). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency, independent of the ratio programmed. The relationship between link port clock frequency, SCLK frequency, and the FSDIV value is expressed by the formula shown below.

If  $f_{LCLK}$  – Link clock frequency,  $f_{LCLK-MAX}$  – Link clock maximum frequency, and  $f_{SCLK}$  – System clock frequency, then:

- $f_{LCLK} = f_{SCLK} < \text{or} = f_{LCLK-MAX}$  if  $DIV = 0$
- $f_{LCLK} = f_{SCLK} / (2 * DIV)$  if  $DIV > 0$

While programming the  $LPDIV$  register to select the clock ratio, make sure that the LCLK frequency does not exceed the maximum frequency supported for the part (see data sheet). For example, if the SCLK frequency is 125 MHz and the data sheet limit for LCLK operation is 83 MHz,  $DIV$  should be greater than or equal to 1, so that LCLK frequency is less than or equal to 83 MHz.

## Multi-Processor Connectivity

The ADSP-BF60x has four link ports and each can operate independently, allowing glueless connection with up to four external processors. All link ports have dedicated DMA channels, allowing independent data transfers. The following figures are some examples of different bus connection topology that can be used in multi-processor system design. The inter-connection methods are not limited to these examples.

**Figure 28-10:** Central Processor Based Model

**Figure 28-11:** Link Port Full-duplex transfer Model

**Figure 28-12:** Link Port Ring Model

The link port protocol doesn't include built in support for multiple masters, although there may be situations where multiple devices try to become the bus master at the same time. Multi-master conflicts may be resolved using token passing. In token passing, the token is a software flag that passes between processors. At reset, the token is set to reside in the link port of one device, making it the master and the transmitter. When a receiver (slave) wants to become the master, it may assert its LACK line to get the master's attention. The master knows, through the software protocol, whether it is supposed to respond with actual data or whether it is being asked for the token. If the master wishes to give up the token, it may send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the slave will set its token and can thereafter transmit. The token release word can be any user-defined value. Since both the transmitter and receiver are expecting a code word, this does not need to be exclusive of normal data transmission. If the master wishes to give up the token, it may send back a user-defined token release word and thereafter clear its token flag. Simultaneously, the slave examines the data sent back and if it is the token release word, the slave will set its token, and can thereafter transmit.

Link port includes handshake for informing enable instance to the other end of transfer (transmit or receive). However, it does not support handshakes to inform disable instance, while a chunk of data is being transferred. Application has to assume about the disabled state of the other end, and then take necessary actions. Similarly, there can be a situation in multi-processing environment where receiver did not read its full FIFO for a long time (owing to internal bus arbitrations etc). In such a case, transmitter may need some software / timer peripheral based time out to inform application that LACK is low for a long time.

## LP Operating Modes

The link port does not have particular modes of operation, as the peripheral is based on a simple protocol. The data transfer modes, Core based and DMA based are explained here.

## LP Data Transfer Modes

This section describes link port DMA and core data transfers.

### DMA Data Transfers

Dedicated DMA channels are available for each link port. DMA related activity is explained below.

1. **Data Receive:** Once the DMA channel and Link port module are configured and enabled, the external device begins writing data to the FIFO through the link port data pins. The FIFO detects this and in turn sends a DMA request. After the request is granted, the DMA transfer progresses until the FIFO is empty.
2. **Data Transmit:** Once the DMA channel and link port module are configured and enabled, setting the `LPEN` bit automatically asserts a DMA request when the TX FIFO is empty. After the request is granted, DMA transfer is performed filling the FIFO. The external device begins reading data from the FIFO through the link port data pins. The FIFO detects that there is room in the buffer and asserts another DMA request, continuing the process.

### Core Data Transfers

If DMA is disabled for a link port buffer, then the internal FIFO buffers may be written or read by the processor core as a memory-mapped register through the MMR access bus. In order to avoid FIFO overflow or underflow, the core should access the FIFO registers in one of the two following ways.

1. Access link port registers using an interrupt service routine (ISR) mapped to the link port data request interrupt. The link port interrupt request remains high only if the FIFO is accessible (if the FIFO is not full in transmit mode and not empty in receive mode).
2. Poll the FIFO status bits of `LPSTAT` register. Write to the Transmit FIFO if not full or read from the Receive FIFO if not empty.

## LP Event Control

This section describes how interrupts and status signals are used with the link ports.

## LP Interrupt Signals

Each link port has two dedicated interrupt lines registered with the System Event Controller: one Data Request interrupt and one Status interrupt. Data request interrupt is asserted with respect to FIFO conditions for data transfer and Status interrupt is asserted when Service Request status or Overflow status is set. Each of these interrupts are explained below.

- Data Request Interrupt.

This is asserted if FIFO is not full in transmission mode and FIFO is not empty in reception mode. This serves as a core triggered interrupt in non-DMA mode and as the DMA interrupt request in DMA mode. Generation of this interrupt is tied to the FFST (link port buffer status bit) in the LPSTAT register.

- Link Port Transmit Service Request Interrupt (LTRQ)

Link port service request interrupts allow a disabled link port to generate an interrupt when an external access is attempted. When a link port is configured as transmitter, Transmit Service Request Interrupt is enabled by setting the LTRQ\_MSK bit in the LPCTL register. When this bit is set, an external receiver can indicate to the disabled transmitter that it needs to receive data through the connected link port. The receiver does so by driving a high level on the LACK line. When the LACK of the disabled transmitter link port is detected high, a LTRQ interrupt is generated, and the transmitter can enable itself for data transfer with the receiver. Note that a pull down on LACK is required for proper function of this feature.

- Link Port Receive Service Request Interrupt (LRRQ)

When a link port is configured as receiver, Receive Service Request Interrupt is enabled by setting the LRRQ\_MSK bit in the LPCTL register. When set, an external transmitter can indicate to the disabled receiver that it needs to receive data through the connected link port. The transmitter does so by driving the first data out. When the LCLK of the disabled receiver link port is detected high, a LRRQ interrupt is generated, and the receiver can further enable itself for data transfer with the transmitter. Note that a pull down on the LCLK signal is required for proper function of this feature.

- Link Port Receive Overflow Interrupt (LPOVF)

This interrupt is generated when the receiver FIFO overflows and is enabled by setting the LPOVF\_MSK bit in the register. This may happen if the transmitter continues to transmit data even though the receiver has de asserted LACK thereby causing the receive FIFO to overflow.

## Enabling Link Port interrupts

A data request interrupt is fed to the System Event Controller directly and can be controlled separately from the application.

Service interrupts and the Overflow interrupt can be masked by setting the corresponding mask bits in LPCTL register, as these are OR'ed and fed to the SIC as a single LPSTAT interrupt. These interrupts are latched and stored in the associated bits of LPSTAT register. If an LPSTAT interrupt occurs, in the ISR, programs should read the LPSTAT register bits to determine the type of interrupt. Note that these bits are write-one-to-clear (W1C); writing one to the bit resets the bit and disables the corresponding interrupt.

## LP Status and Error Signals

This section explains the various status signals in the LPSTAT register.

- Transfer Status signals

Link port bus status (LPBS): This bit gives the status of bus busy/idle condition, when the link port is configured as transmitter. The LPBS is kept high if data is being driven by the link port in to the link port pins. Programs may poll this bit after polling the FFST bit to safely disable the link port.

Link buffer status (FFST): This field directly indicates the status of the FIFO (including empty / full conditions) during data transfer. Software can poll this field in link port status register before writing in to FIFO (in case of transmission) or reading from FIFO (in case of reception). The FFST bit is automatically cleared when the link port is disabled.

- Transfer Request Status signals

Link port receive request status (LRRQ) / link port transmit request status (LTRQ): These bits indicate that an external receiver wants to receive data (in case the link port is a disabled transmitter) or an external transmitter wants to send data (in case the link port is a disabled receiver). Software can poll this bit to enable the transmitter or receiver accordingly.

- Error Status signals

Link buffer error status (LERR): In receive mode 32-bit data is received in four chunks of 8-bit data. This is then packed to a single 32-bit data before loading the FIFO. The LERR bit is high during this packing process and goes low after packing.

Link port overflow status (LPOVF): This bit is set when the receive FIFO overflows. This may occur if the transmitter continues to transmit data even though the receiver has de asserted LACK thereby causing the receiver FIFO to overflow.

## LP Programming Model

The following sections provide information on configuring the operating mode and enabling the link ports.

- [\*Setting Up LP DMA Transmit Operation\*](#)
- [\*Setting Up LP DMA Receive Operation\*](#)
- [\*Setting Up LP Core Transmit Operation\*](#)
- [\*Setting Up LP Core Receive Operation\*](#)

## Setting Up LP DMA Transmit Operation

This section describes the steps for configuring the link ports in DMA transmit mode.

1. Enable the link port pins in the GPIO Port Mux using the appropriate Port FER and Port MUX registers.
2. Install interrupt handlers for DMA and for transfer status (Service Request Interrupt).
3. Configure the link port to transmit by setting the LP\_CTL bit and enable the transmit request interrupt mask by setting the TRQMSK bit.
4. Program the link port clock divider by writing a value to the LP\_DIV register.
5. If using DMA Stop mode/Auto Buffer mode, program the DMA registers.

*ADDITIONAL INFORMATION:* An example configuration is: Start Address, XCount, Xmodify and Config (Stop/Auto, Psize=1, Msize=4, Interrupt generation and Memory Read.

6. If using DMA Stop mode/Auto Buffer mode, program DMA Registers.  
*ADDITIONAL INFORMATION:* An example configuration is: Start Address, XCount, Xmodify and Config (Stop/Auto, Psize=1, Msize=4, Interrupt generation and Memory Read.
7. Wait for the link port receiver (connected externally) to be enabled. The application can wait for the transmit service request interrupt to assert.
8. Clear the transmit service request interrupt status by writing 1 to the LP\_STAT.LTRQ bit.
9. Enable DMA by setting the EN bit in the DMA configuration register.
10. Enable the link port by setting the LP\_CTL.EN bit.
11. Wait for DMA to assert transfer completion interrupt.
12. Clear the DMA interrupt source by writing 1 to the IRQDONE bit of the DMA status register.

## Setting Up LP DMA Receive Operation

This section describes steps for using the link ports in receive mode of DMA

1. Enable link port pins in GPIO Port Mux using the appropriate Port FER and Port MUX registers.
2. Install interrupt handlers for DMA and for transfer status (Service Request Interrupt).
3. Configure the link port for reception (clear the LP\_CTL.TRAN bit) and enable the receive request interrupt mask by setting the LP\_CTL.RRQMSK bit.

4. If using DMA Stop mode/Auto Buffer mode, program the DMA registers.

*ADDITIONAL INFORMATION:* An example configuration is: Start Address, XCount, Xmodify and Config (Stop/Auto, Psize=1, Msize=4, interrupt generation and memory write).

5. If using DMA Array mode/List mode, create DMA configuration data structures filled with components.

*ADDITIONAL INFORMATION:* An example configuration is: Start Address, XCount, XModify, Config (Array/List, Psize=1, Msize=4, Interrupt generation, Memory Write and Fetch=4/5) and Next Desc pointer (if List mode). Further program DMA configuration register (Array/List, Psize=1, Msize=4, Memory Write and Fetch=4/5) and program Next Desc pointer (if list mode).

6. Wait for the link port transmitter (connected externally) to be enabled with subsequent data transmission. The application can wait for Receive Service Request Interrupt to assert.
7. Clear the receive service request interrupt status by writing 1 to the LP\_STAT.LRRQ bit.
8. Enable DMA by setting the EN bit in the DMA configuration register.
9. Enable the link port by setting the LP\_CTL.EN bit.
10. Wait for DMA to assert the transfer complete interrupt.
11. Clear the DMA interrupt source by writing 1 to the IRQDONE bit of the DMA status register.

## Setting Up LP Core Transmit Operation

This section describes steps for using the link ports in processor core based transmission.

1. Enable the link port pins in the GPIO Port Mux using the appropriate Port FER and Port MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source/ID as the DMA interrupt line in the SEC.
3. Configure the link port for transmission by setting the LP\_CTL.TRAN bit) and enable the transmit request interrupt mask by setting the LP\_CTL.TRQMSK bit).
4. Program the link port clock divider by writing a value in to the LP\_DIV register.
5. Wait for the link port receiver (connected externally) to be enabled. The application can wait for a transmit service request interrupt to assert.
6. Clear the transmit service request interrupt status by writing 1 to the LP\_STAT.LTRQ bit.
7. Enable the link port by setting the LP\_CTL.EN bit.
8. The interrupt is asserted whenever there is free space in the FIFO. The application can write to the LP\_TX register based on the FIFO conditions (half or empty) reflected in the LP\_CTL.FFST bit field.

## Setting Up LP Core Receive Operation

This section describes steps for using the link ports in processor core based reception.

1. Enable the link port pins in the GPIO Port Mux using the appropriate Port FER and Port MUX registers.
2. Install interrupt handlers for data transfer and for transfer status (service request interrupt). The interrupt handlers for data transfer are the same source/ID as the DMA interrupt line in the SEC).
3. Configure link port for reception (clear LP\_CTL.TRAN bit) and enable receive request interrupt mask (set LP\_CTL.RRQMSK bit).
4. Wait for the link port transmit (connected externally) to be enabled with subsequent transmission of data. Application can wait for Receive Service Request Interrupt to be asserted.
5. Clear the receive service request interrupt status by writing 1 to the LP\_STAT.LRRQ bit.
6. Enable the link port by setting the LP\_CTL.EN bit.
7. The interrupt is asserted whenever there is free space in the FIFO. The application can read from the LP\_RX register based on the FIFO conditions (1 or 2 or 3 data available) which is reflected in the LP\_CTL.FFST bit field.

## LP Register Descriptions

Link Port (LP) contains the following registers.

**Table 28-5:** LP Module Registers

| Name          | Description                   |
|---------------|-------------------------------|
| LP_CTL        | Control Register              |
| LP_STAT       | Status Register               |
| LP_DIV        | Clock Divider Value           |
| LP_TX         | Transmit Buffer               |
| LP_RX         | Receive Buffer                |
| LP_TXIN_SHDW  | Shadow Input Transmit Buffer  |
| LP_TXOUT_SHDW | Shadow Output Transmit Buffer |

## Control Register

The LP\_CTL register provides LP interrupt masking, selection of transfer direction, and link port enable.

| 0       | LTRQ     | Transmit Request.<br>The LP generates this interrupt when the LP_ACK pin of a disabled link port (the transmitter) is forced high by another link port (the receiver).                                                            |

## Clock Divider Value

The LP\_DIV register selects the divisor for ratio between the internal LP clock (LCLK) and system clock (SCLK). This programming is applicable only for the transmitter. The receiver can operate at any asynchronous frequency up to the maximum frequency independent of the ratio programmed.

**LP\_DIV: Clock Divider Value - R/W**

Reset = 0x0000 0000

**Figure 28-15:** LP\_DIV Register Diagram

**Table 28-8:** LP\_DIV Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                    |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | <p>Divisor Value.</p> <p>The LP_DIV.VALUE bits select the clock divider (relating the LP' internally generated clock (LCLK) to the system clock (SCLK). The LP_DIV.VALUE should be programmed prior to LP enable.</p> <p>For LP_DIV.VALUE = 0, LCLK = SCLK</p> <p>For LP_DIV.VALUE = xxxxxxxx, LCLK = SCLK / (2 x DIV)</p> |

## Transmit Buffer

The LP\_TX register buffers the transmit data flow through the LP. The transmit buffer is a two-location deep FIFO. In the transmit buffer, the input stage of the FIFO is used to accept core data or DMA data from internal memory, and the data is transferred to the ports from the output stage of the FIFO. The output stage performs the unpacking in the transmit buffer. The least significant byte is transmitted first. As each word is unpacked and transmitted, the next location in FIFO becomes available and a new DMA request is made if DMA is enabled. If the register becomes empty, the LP asserts the LP\_CLK signal. For more information on LP buffer features and operations, see the LP functional description.

**LP\_TX: Transmit Buffer - R/W**

Reset = 0x0000 0000

**Figure 28-16:** LP\_TX Register Diagram

**Table 28-9:** LP\_TX Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | DATA     | Transmit Data Buffer.   |

**Receive Buffer**

The LP\_RX register buffers the receive data flow through the LP. The receive buffer is a four-location deep FIFO. In the receive buffer, data is transferred to the core or DMA from the receive FIFO where an internal register does the packing. This packing register is not software accessible. For more information on LP buffer features and operations, see the LP functional description.

**LP\_RX: Receive Buffer - R/W**

Reset = 0x0000 0000

## 29 Video Subsystem (VID)

The ADSP-BF60x features a sophisticated video subsystem (VID) consisting of the following functional blocks:

- Three Video Ports (PPI)
- The Pixel Compositor (PIXC)
- The Pipelined Vision Processor (PVP)
- The Video Interconnect
- 18 DMA Channels

The enhanced parallel peripheral interfaces (EPPIs) can operate in video input and video output modes, and also support several general-purpose modes of operation. The EPPIs are aware of video frame synchronization, blanking concepts and color formats. They can receive up to 16-bit video data directly from video sensors (cameras) and also directly control displays on the output.

The pixel compositor (PIXC) supports color space conversion and alpha blending for video overlays.

The pipelined vision processor (PVP) is a framework for various vision processing elements, which are targeting mainly edge and object detection strategies.

The video interconnect is a local, distributed bus system, which interconnects the EPPI ports, the PIXC and the PVP.

### VID Features

The following is a brief list of the features of the video subsystem.

- Bandwidth-saving pre-processing and post-processing on video inputs and outputs
- Video analytics and color-space conversion during video reception
- Alpha blending during video transmission
- Concurrent memory-to memory co-processing

### VID Functional Description

The following sections provide a functional description of the VID.

## VID Register List

The VID selects connections for the PVP and PPI modules, configuring connections to use these peripherals for video operations. Also, the VID selects broadcast or non-broadcast mode for handling the receive Y channel data. Note that these connections are static and have to be configured before enabling the PPI, PIXC, and PVP blocks. A set of registers govern VID operations. For more information on VID functionality, see the VID register descriptions.

**Table 29-1:** VID Module Registers

| Name     | Description                      |
|----------|----------------------------------|
| VID_CONN | Video Subsystem Connect Register |

## VID Block Diagram

The [VID Block Diagram](#) shows an overview of the video subsystem including the PIXC, PVP, and EPPI.

**Figure 29-1:** VID Block Diagram

## VID Architectural Concepts

Traditionally, the three EPPIs operate in DMA mode and as such mainly transport data between external world and on-chip L1 and/or L2 SRAM or external L3 memories. Each EPPI interface contains two DMA channels. The primary one is used for general data or alternatively only for the luminance component. The secondary can be optionally used for chrominance.

## PIXC and PVP Co-Processing

The PIXC and PVP processors can operate in coprocessor mode. In this mode, the two blocks receive input data from system memory via dedicated input DMA channels, process it, and then store the results back to system memory using dedicated output DMA channels. For this memory-to-memory operation, the PIXC features two input DMA channels, one for the background image and one for the overlay, and also an output DMA channel to store the results back to memory. Similarly, the PVP has a DMA channel pair of input and output for memory-to-memory operation. This concept is referred to as the camera pipe.

Before data is processed by the PVP processing elements, it can be preconditioned by the input formatter IPF1. Results can be post-conditioned by the output formatter OPF3.

The following figure illustrates the coprocessor architecture. First video data is received by one of the EPPI interfaces and stored into the system memory. Then, the PIXC and PVP processors have access to the data as the Blackfin cores do. All processing units may process the data either in parallel or serial fashion.

**Figure 29-2:** Coprocessor Topology

When visualizing a typical signal flow in coprocessor topology as in [Coprocesor Topology](#), a few characteristics of this topology become obvious. On the positive side, each block can be used multiple times (time domain multiplexing) for different jobs when processing one set of data. There is perfect flexibility in order of operations. However, fundamental rules of multi-processing apply—processing threads have to be synchronized when an operation is dependent on the results of operations performed by any other processing unit. Furthermore, each hand-over is performed through system memory. This requires a significant amount of memory as well as substantial memory bandwidth.

**Figure 29-3:** Coprocessor Signal Flow Example

## PIXC and PVP Preprocessing

The PIXC and PVP processors can also operate in preprocessing mode in order to conserve memory bandwidth and reduce power dissipation.

When in receive mode, each EPPI can perform data broadcasting on its main (luminance) channel. Received data is forwarded to the DMAs and the video interconnect simultaneously. The PIXC and the

PVP can receive video data from the video interconnect. This way, the PIXC and/or PVP can preprocess received video data before DMA stores it to memory.

**Figure 29-4:** EPPI Data Broadcast to DMA, PIXC, and/or PVP

*EPPI Data Broadcast to DMA, PIXC, and/or PVP* illustrates that a receiving EPPI can broadcast data to up to three destinations: to the memory via DMA, to the PIXC and the PVP via video interconnect. When the PIXC receives data from any of the three EPPIs it operates in color space conversion mode and its overlay DMA input is not used.

Neither direct EPPI-to-EPPI operation nor EPPI-to-PIXC-to-EPPI operation is supported. However, the PIXC and PVP can operate in the same pipe as shown in the figure below.

**Figure 29-5:** PPI, PIXC and PVP Chaining in Preprocessing Pipe

This mode is useful when the EPPI receives color data in RGB format. The PIXC can transform it to YCrCb format so that the PVP finally processes the Y in monochrome fashion. The PIXC does not support data broadcasting to both DMA and video interconnect. Either the PIXC output is written to memory or forwarded to the PVP.

When the PVP receives data from the EPPIs or the PIXC through the video interconnect, the data can be processed by up to three camera pipes. Data is preconditioned by the input formatter IPF0. Similarly, the result of each camera pipe can be post-conditioned by the respective output formatters OPF0, OPF1 and OPF2 and is then written to system memory via dedicated DMA channels.

Whenever the PIXC and PVP operate in a common pipeline, the data must be sourced by one of the EPPIs. Whenever a EPPI is used as the source for a PIXC and/or PVP pipe, the respective EPPI must operate in external clock mode.

## PIXC Post Processing

The pixel compositor can perform post-processing. In this mode, video frames residing in system memory can be transmitted via DMA, while the PIXC applies an overlay and can convert the color space before the resulting data is forwarded to any of the EPPIs via video interconnect.

**Figure 29-6:** PIXC and PPI Chaining in Post-processing Pipe

When in post-processing mode, the PIXC must receive data from the DMAs, it cannot receive data from another EPPI through video interconnect.

## Concurrency of Pre-, Co- and Post-Processing

Pre-, co- and post-processing are not mutually exclusive concepts. In general a mix of all three topologies is often the best strategy for applications. The following figure shows an example where the PVP's camera pipes operate in preprocessing mode, its memory pipe operates in co-processing mode, and the finally the PIXC does post-processing.

**Figure 29-7:** Concurrency of Pre-, Co- and Post-Processing

The pre- and post-processing elements typically operate in a static or pseudo static configuration. Certainly, the various coefficients, like filter settings and overlay regions may dynamically change from frame to frame. The basic data flow and operation mode, however, tends to be static over time or over at least a period of time. The co-processing elements are different in nature, they typically perform a job in any desired mode and are then reconfigured for a complete different job (time domain multiplexed). The PVP memory pipe has been designed to perform complete job list without support required from the Blackfin cores.

## VID Status and Error Signals

The video subsystem does not have dedicated status or error interrupts. However, the VID signals errors to the associated EPPI peripheral when stall or overflow conditions occur. While the PVP has been designed to never stall on the video interconnect, the PIXC may do so. This is reported by the `PxPERR` flag to the `PPIX_STAT` register. If the PIXC and the PVP are configured to receive data from the same EPPI input, the error flag only signals the stalling condition of the PIXC. The PVP continues to get new data.

## VID Programming Model

The video subsystem is typically configured in static or pseudo-static fashion. There is only one MMR, the `VID_CONN` register, which needs to be written before the EPPI, PIXC and PVP can be enabled. When programs must alter `VID_CONN` at run time, it is important that all impacted video blocks are disabled.

The `VID_CONN.PIXCOIN` bit field controls whether the PIXC receives input from DMA or from a designated EPPI port. Similarly, the `VID_CONN.PVPOIN` bit field determines the data source of the PVP. When altering the `VID_CONN.PIXCOIN` bit field, the PIXC and both the former and the newly selected EPPIs need to be disabled. However, the other PPI and the PVP may continue operation without being disturbed.

For EPPIs operating in transmit mode, the three `VID_CONN.PPIxTX` bit fields control whether the respective PPI module receives data from DMA channel or from the PIXC. Only out of the PPIs or the PVP or the DMA can receive data from PIXC at a time.

For EPPIs operating in receive mode, the three `VID_CONN.PPIxBCST` bits enable broadcasting of the main (luminance) input data. The bits only need to be set (=1) if received data is broadcast to both the video interconnect and DMA system. If not set (=0), the `VID_CONN.PIXCOIN` and `VID_CONN.PVPOIN` bits determine whether data goes to either the video interconnect or to the DMA system. Broadcasting only takes place if indeed at least one of `VID_CONN.PIXCOIN` or `VID_CONN.PVPOIN` bit fields instruct the modules to consume data from the respective EPPI.

Care must be taken to ensure that the configuration of the EPPIs, PIXC and PVP works with the VID settings in a meaningful way. Also, if significant mode switching takes place on one module, the other modules shall always be temporarily disabled.

## VID Performance

The maximum EPPI frequency is 83 MHz. Assuming each clock contains a valid pixel, the maximum pixel rate is 83 MPixels/s. The same limitation also applies to the PVP's memory pipe. Unless the base clock (SCLK0) is lower than 83 MHz, memory pipe throughput is  $SCLK0/2$ . The PIXC can operate at full SCLK0 speed in memory-to-memory mode. The bandwidth consumed by memory-to-memory operations of the PVP and the PIXC can be controlled via the bandwidth control functionality of the respective DMA channels. Similarly, the consumed bandwidth can be monitored by the bandwidth monitor functionality of the DMA channels.

## VID Register Descriptions

Video Subsystem Registers (VID) contains the following registers.

Table 29-2: VID Module Registers

| Name     | Description                      |
|----------|----------------------------------|
| VID_CONN | Video Subsystem Connect Register |

Video Subsystem Connect Register

The VID\_CONN selects connections for the PVP and PPI modules, configuring connections to use these peripherals for video operations. Also, the VID\_CONN selects broadcast or non-broadcast mode for handling the receive Y channel data. Note that these connections are static and have to be configured before enabling the PPI, PIXC, and PVP blocks.

VID\_CONN: Video Subsystem Connect Register - R/W

Reset = 0x0000 0000

|         |           | 0 Non-broadcast mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |           | 1 Broadcast mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 21      | PPI0BCAST | PPI_0 Broadcast Mode.<br>The VID_CONN.PPIOBCAST selects broadcast or non-broadcast mode for receive Y channel data. This bit is valid only when PPI_0 is in receive mode, and either VID_CONN.PIXCOIN = 0x1 or VID_CONN.PVPOIN = 0x1. In broadcast mode, the receive Y channel data is send on both the PxP interface and the PPI_0 DMA channel 0. In non-broadcast mode, the receive Y channel data is sent to either the PxP interface or the PPI_0 DMA channel based on the VID_CONN.PIXCOIN and VID_CONN.PVPOIN bits programming. |
|         |           | 0 Non-broadcast mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |           | 1 Broadcast mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 30 Pipelined Vision Processor (PVP)

The Pipelined Vision Processor (PVP) provides a set of 12 high-performance signal processing blocks that can be flexibly combined to form streaming data processing pipes. These blocks are optimized for tasks typical of video and image processing, analytics (e.g. advanced driver assistance systems), robotics, and 2-dimensional vector applications. The PVP works in conjunction with the processor core(s). It is optimized for convolution and wavelet-based object detection, classification, tracking, and verification algorithms. The PVP bundles a set of processing blocks required for high-speed 2-dimensional digital signal processing.

Most blocks are optimized for 2-dimensional video analytics operations and can be re-purposed for general-purpose operations. Other blocks have general-purpose functionality and might be used in a variety of applications outside of video processing.

### PVP Features

The PVP contains a number of highly configurable blocks that provide a broad set of pixel processing features:

- Variety of 1<sup>st</sup>-derivative and 2<sup>nd</sup>-derivative edge detection and classification methods
- Quad 5x5 convolution kernels with 8300 MMACS total
- Integral of pixels, variances, magnitudes and gradients
- Thresholds and histograms
- General-purpose 32-bit divider, multiplier, adder, and accumulator
- Up to 1280 x 960 pixel progressive video
- Up to 83M Pixels/second on each of up to four pipes
- Bandwidth-saving pre-processor architecture with data broadcasting to three “camera pipes”
- Memory-to-memory co-processing with autonomous sequencing of job lists
- Concurrent pre- and co-processing autonomous update of coefficients at frame boundaries
- Autonomous update of coefficients at frame boundaries

## PVP Functional Description

The Pipelined Vision Processor consists of 12 signal processing blocks, two input formatters and four output formatters. In combination and for simplicity, these elements are referred to as processing blocks.

The following sections describe all of the blocks that make up the PVP module. It provides details on their operation and interaction with each other and the processor core.

## PVP Register List

The pipelined vision processor PVP implements the signal and image processing algorithms that are required for pre-processing of video frames in advanced driver assistance systems (ADAS) applications. A number of processing blocks contribute to PVP operations. These include:

- Convolution/Down-scaling engine (CNV)
- Pixel Magnitude and Angle computation unit (PMA)
- Threshold, Histogram and Compression engine (THC)
- Arithmetic Computation Unit (ACU)
- Pixel Edge Classifier (PEC)
- Integral Image computation (IIM)
- Up-Down Scaler (UDS)

In addition to these processing blocks, the PVP also has a number of blocks that permit interfacing to other modules ( , ) and provide control for PVP operations:

- Input data formatter ( IPF )
- Output data formatter (OPF)
- Image pipe controller (IPC)

A set of registers govern PVP operations. For more information on PVP functionality, see the PVP register descriptions.

**Table 30-1:** PVP Module Registers

| Name      | Description      |
|-----------|------------------|
| PVP_REVID | Revision ID      |
| PVP_CTL   | Control          |
| PVP_IMSKn | Interrupt Mask n |

**Table 30-1:** PVP Module Registers (Continued)

| Name               | Description                        |
|--------------------|------------------------------------|
| PVP_STAT           | Status                             |
| PVP_ILAT           | Interrupt Latch Status n           |
| PVP_IREQn          | Interrupt Request n                |
| PVP_OPFn_CFG       | OPFn (Camera Pipe) Configuration   |
| PVP_OPFn_CTL       | OPFn (Camera Pipe) Control         |
| PVP_OPF3_CFG       | OPF3 (Memory Pipe) Configuration   |
| PVP_OPF3_CTL       | OPF3 (Memory Pipe) Control         |
| PVP_PEC_CFG        | PEC Configuration                  |
| PVP_PEC_CTL        | PEC Control                        |
| PVP_PEC_D1TH0      | PEC Lower Hysteresis Threshold     |
| PVP_PEC_D1TH1      | PEC Upper Hysteresis Threshold     |
| PVP_PEC_D2TH0      | PEC Weak Zero Crossing Threshold   |
| PVP_PEC_D2TH1      | PEC Strong Zero Crossing Threshold |
| PVP_IIMn_CFG       | IIMn Configuration                 |
| PVP_IIMn_CTL       | IIMn Control                       |
| PVP_IIMn_SCALE     | IIMn Scaling Values                |
| PVP_IIMn_SOVF_STAT | IIMn Signed Overflow Status        |
| PVP_IIMn_UOVF_STAT | IIMn Unsigned Overflow Status      |
| PVP_ACU_CFG        | ACU Configuration                  |
| PVP_ACU_CTL        | ACU Control                        |
| PVP_ACU_OFFSET     | ACU SUM Constant                   |
| PVP_ACU_FACTOR     | ACU PROD Constant                  |

**Table 30-1:** PVP Module Registers (Continued)

| Name              | Description                                |
|-------------------|--------------------------------------------|
| PVP_ACU_SHIFT     | ACU Shift Constant                         |
| PVP_ACU_MIN       | ACU Lower Sat Threshold Min                |
| PVP_ACU_MAX       | ACU Upper Sat Threshold Max                |
| PVP_UDS_CFG       | UDS Configuration                          |
| PVP_UDS_CTL       | UDS Control                                |

## PVP Block Diagram

The following figure shows the PVP block diagram. For more information on parts of this diagram, see the corresponding section of the [PVP Functional Description](#) or see [Architectural Concepts](#).

**Figure 30-1:** PVP High-Level Block Diagram

## Input Formatters (IPFx)

The PVP features two input formatters. The camera pipe is served by input formatter 0 (IPF0), where data is received directly from the video subsystem and the memory pipe is served by input formatter 1 (IPF1) where data is received from DMA. The input formatters master the entire pipe associated with them. Data received by IPF0 can be broadcast and is sent to the DMA system via output formatters OPF0, OPF1 and OPF2. Data received by IPF1 is sent to the DMA system via output formatter 3 (OPF3). The input formatters are responsible for the following tasks.

- Formatting input data
- Extracting color or luminance components
- Windowing

- Separating odd and even pixels
- Frame count
- Status report control

The following tables illustrate input formatter connections. The data source is fixed to video subsystem for IPF0 and to the data input DMA for IPF1. Note that s16 = 16-bit signed data and u16 = 16-bit unsigned data etc.

**Table 30-5:** IPF0 Block Connectivity

| Input 0            |      | Input 1 |      | Output 0   | Output 1   | Output 2 |
|--------------------|------|---------|------|------------|------------|----------|
| s16, u16, s32, u32 |      |         |      | s32        | s32        | s32      |
| Block              | Port | Block   | Port |            |            |          |
| VSS                | 0    | N/A     | N/A  | Full Frame | Odd/Window | Even     |

**Table 30-6:** IPF1 Block Connectivity

| Input 0            |      | Input 1 |      | Output 0   | Output 1 | Output 2 |
|--------------------|------|---------|------|------------|----------|----------|
| s16, u16, s32, u32 |      |         |      | s32        | s32      | s32      |
| Block              | Port | Block   | Port |            |          |          |
| DMA                | 0    | N/A     | N/A  | Full Frame | Odd      | Even     |

Both input formatters feature three 32-bit outputs that can be individually enabled by the respective `PVPO_IPFx_CTL.OPORTyEN` bits. All three outputs can operate in parallel. Output port 0 always outputs all data words, if enabled.

## Odd/Even Outputs

The IPF output ports 1 and 2 can partner in a way that all even-indexed data words output via port 2 and all odd-indexed data words output via port 1. In this mode, the even-indexed data words are delayed by one clock cycle where a pair of even/odd words leaves the IPFx simultaneously. The following figure illustrates the value of this feature:

**Figure 30-2:** Separation of Odd and Even Data Words

For example, if the arithmetic control unit (ACU) is configured to perform division operations in memory pipe mode, it expects the numerator on its X input and the denominator on its Y input. The memory pipe receives all data in a single DMA channel (that may operate in 2-dimensional mode). The DMA may provide a series of interleaved numerator/denominator pairs. The IPF1 splits the data words as required. The resulting quotients are then sent to DMA by the output formatter OPF3.

## Windowing

Alternatively, in camera pipe mode the IPF0's output port 1 can output only the pixels which belong inside of the window coordinates as specified by the PVP\_IPF0\_HPOS, PVP\_IPF0\_VPOS, PVP\_IPF0\_HCNT and PVP\_IPF0\_VCNT registers.

**Figure 30-3:** Definition of Port 1 Window Coordinates

The IPF1 (memory pipe) does not support windowing this way. Rather, the PVP\_IPF1\_HPOS and PVP\_IPF1\_VPOS registers are unused. The PVP\_IPF1\_HCNT and PVP\_IPF1\_VCNT registers are required to

match the `XCNT`, `YCNT` and `MSIZE` settings of the input data DMA. Window coordinates apply after color extraction, therefore consider the color format selected by the `PVP_IPF1_CTL.CFRMT` bit field.

## Monochrome Data Reception

Data is received from video subsystem (IPF0) or from data input DMA (IPF1) through 32-bit buses and IPF1 can receive 32-bit data words from the DMA. However, video pixels are typically represented by 16-bit data entities. For best system efficiency, pairs of 16-bit data words can be packed by the data source. The DMA controller enables 32-bit packing by the `DMAx_CFG.PSIZE = 2` bit setting. The parallel peripheral interfaces (PPIs) and the pixel compositor (PIXC) send packed color formats or the PPIs enable packing by the `PPIx_CTL.PACKEN` bit. Either way, both IPFs can unpack the incoming data to two 16-bit entities when the `PVP_IPFx_CTL.UNPACK` control bit is set.

The IPFs always output 32-bit words. By default, incoming data is zero extended to 32 bits. The `PVP_IPFx_CTL.SIGNEXT` bit changes the behavior to sign extension. The setting of the `PVP_IPFx_CTL.CFRMT` field determines how many significant bits the incoming data has. Monochrome data can have 8, 16, 24 or 32 significant bits. Note that, if the PPI receives 10-, 12- or 14-bit data it performs zero/sign-extension to 16 bits. In special color formats the IPF also extends from 5 or 6 significant bits.

Dimensions of a frame supplied to IPF0 and IPF1 generally must be a multiple of four. Further restrictions may apply by specific PVP blocks, especially if the odd/even ports are used or complex CFRMT formats are selected.

## Receiving Unsigned Data

Received video data is typically 8, 10, 12 or 14 bits wide and zero extended to 16-bit values. Therefore, pixels can always be positive values whether processed by signed or unsigned computation engines. If received data is however truly 16 or 32 bits wide it matters whether data is processed the signed or the unsigned way.

If the received data is 16- or 32-bit unsigned data and the IPFs forward the data to functional blocks that can only operate on 16-bit signed (CNVx, PMA) or 32-bit signed (ACU) data format, conflicts can occur. To avoid these conflicts, the `PVP_IPFx_CTL.QFRMT` bit instructs the IPF to right shift the incoming data by one bit position and to fill the most significant bit with a zero value. This way, the input is always interpreted as a positive value by signed engines. The output formatter (OPFx) blocks provide the counterpart functionality, which shifts the result back to the left by one bit position. This way, conflicts due to signed bits are avoided for the cost of losing one bit of input accuracy.

## Color Extraction

The PVP processes in monochrome data format. However, its data inputs often have to probe color data streams. Therefore, the IPFs feature a variety of features that allow extraction of certain luminance or chromatic values out of composite colored data streams. These features include:

- Extraction of Y (luma) values out of YCrCb streams
- Extraction of G (green) values out of RGB streams

- Extraction of G (green) values out of Bayer streams
- Extraction of R (red) values out of Bayer streams

The PVP\_IPFX\_CTL.CFRMT bit field defines what color format is used on the incoming data. The table “Supported Monochrome and Color Video Formats” provides the overview where each cell shows two consecutive 32-bit words that follow the conventions shown below. This refers to data sent by EPPI/PIXC in case of IPF0 and data stored in memory (and fetched by DMA) for IPF1.

|                  |                 |                 |                  |
|------------------|-----------------|-----------------|------------------|
| 1st word MS byte | 1st word byte 2 | 1st word byte 1 | 1st word LS byte |
| 2nd word MS byte | 2nd word byte 2 | 2nd word byte 1 | 2nd word LS byte |

For simplicity, YUV terminology is used rather than YCrCb. Items marked with \* indicate that multiple options are commonly used in industry standard, but there is no difference for the PVP as Cr and Cb components are discarded.

**Table 30-7:** Supported Monochrome and Color Video Formats

The IPFs process all data words for the monochrome input format. For YCrCb formats, the IPFs discard the Cr and Cb color components and only process the luminance values Y. With RGB formats the PVP\_IPFx\_CTL.EXTRED bit is used. If cleared, the IPFs extract the green components. If set, the IPFs extract the red components.

On top of the streaming formats shown in the table above, the IPFs can also extract color components out of Bayer pattern matrices as shown in the figure below.

**Figure 30-4:** Supported Bayer Patterns

If the PVP\_IPFx\_CTL.EXTRED bit =0, the IPFs extract the green components of the Bayer matrix. The output frame has half the horizontal resolution of the input frame. If the PVP\_IPFx\_CTL.EXTRED bit =1, the IPFs extract the red component, dividing horizontal and vertical resolution.

In Bayer extraction mode, the input values can be 10, 12 or 16 bits wide. An 8-bit format is not supported. The PPI's SWAPEN bit must be cleared in this mode.

The Bayer concepts can also apply to red-clear-clear-clear (RCCC) data. This is similar to Bayer format, except that the green and blue pixels have monochrome (clear filter) values. Programs have then the following options:

- Extract the red pixels as in Bayer extraction mode.
- Extract one clear pixel by swapping type 1 vs. type 2 and setting the EXTRED bit.
- Extract the diagonal clear pixels that correspond to the green pixels in Bayer format.
- Use the odd/even mechanism and only process the clear columns.
- Ignore the fact that red pixels are special and low-pass them using convolution blocks.

## Pipe Mastering

Beside formatting and broadcasting incoming data, the IPFs master the camera and memory pipelines. For a description of that functionality, see the Programming Model section.

## PPI and PVP Interoperability

If IPF0 is receiving data from any of the PPIs in camera pipe mode, the settings of the two modules need to partner for reception of reasonable data formats. The following Table lists the supported combinations of settings.

**Table 30-8:** Matching PPI and PVP Settings

| Pixel<br>Format<br>on PPI<br>pins | PPI settings |          |                                                |                                                                    |                                 |                                 |                                                          | PVP Settings |                      |                       |                                    |

## Output Formatters (OPFx)

The output formatters collect the data results of PVP processing blocks, apply final formatting and then forward the results to the DMA channels. The OPF0, OPF1 and OPF2 formatters serve the three camera pipes, while OPF3 serves the memory pipe. Each OPF is associated with a specific DMA channel. The single input is widely configurable as shown in the following tables.

**Table 30-9:** OPF0, OPF1, OPF2 Block Connectivity

| Input 0            | Input 1 | Output 0           | Output 1 | Output 2 |

## Data Packing

To ensure efficient memory bandwidth use, the OPFs support data packing. Ideally, the PVP results are packed into 32-bit entities and forwarded to the DMA channel, which is also programmed to 32-bit mode by setting `PVP_OPFx_CTL.OSIZE = 0` and the `DMA_CFG.PSIZE = 2` for each respective DMA channel.

The `PVP_OPFx_CTL.ISIZE = 0` setting instructs the OPF to accept a full 32-bit word from the data source. In this case, packing is not possible and `PVP_OPFx_CTL.OSIZE = 0` and `DMA_CFG.PSIZE = 2` are mandatory settings.

The `PVP_OPFx_CTL.ISIZE = 1` setting instructs the OPF to accept 16-bit words from the data source. In this case the user has multiple options. If packing is desired, set `PVP_OPFx_CTL.OSIZE = 0` and `DMA_CFG.PSIZE = 2`. Otherwise, these bit fields are set to `PVP_OPFx_CTL.OSIZE = 1` and `DMA_CFG.PSIZE = 1` for 16-bit transfers between OPF and DMA channel. The `PVP_OPFx_CTL.IUP16` bit determines whether the OPFs latch the lower 16 bits or the upper 16 bits from their 32-bit input.

When `PVP_OPFx_CTL.ISIZE = 2` the OPF to accepts 8-bit bytes from the data source. To pack values to a 32-bit output, set `PVP_OPFx_CTL.OSIZE = 0` and `DMA_CFG.PSIZE = 2`. To only pack two values into a 16-bit output, set `PVP_OPFx_CTL.OSIZE = 1` and `DMA_CFG.PSIZE = 1`. To disable packing, set `PVP_OPFx_CTL.OSIZE = 2` and `DMA_CFG.PSIZE = 0`. Again, the `PVP_OPFx_CTL.IUP16` bit selects between bits [7:0] and bits [23:16] on the inputs.

The `PVP_OPFx_CTL.ISIZE = 3` setting instructs the OPF to accept 4-bit nibbles from the data source. Nibbles must always be packed to 8-, 16- or 32-bit entities following the rules already described above. This results in dual, quad or octal nibble groups per DMA transfer. The `PVP_OPFx_CTL.IUP16` bit selects between bits [3:0] and bits [19:16] on the inputs.

Note that data packing has requirements for the horizontal size of data frames, which must be a multiple of the packing ratio. The following table summarizes the packing options.

**Table 30-11:** OPF Packing Options

| ISIZE | OSIZE | PSIZE | IUP16 | 32-bit DMA word         |
|-------|-------|-------|-------|-------------------------|
| 0     | 0     | 2     | 0     | D0[31:0]                |
| 1     | 1     | 1     | 0     | 0, D0[15:0]             |
|       |       |       | 1     | 0, D0[31:16]            |
|       | 0     | 2     | 0     | D1[15:0], D0[15:0]      |
|       |       |       | 1     | D1[31:16],<br>D0[31:16] |

**Table 30-11:** OPF Packing Options (Continued)

| ISIZE | OSIZE | PSIZE | IUP16 | 32-bit DMA word                                     |

If the IPF is receiving unsigned data and its `PVP_IPFx_CTL.QFRMT` bit is set, it is helpful that the OPF corrects the shifting position back before results are transmit to DMA. For this purpose, the `PVP_OPFx_CTL.QFRMT` bit shifts the results to the left by one bit position.

## Output FIFOs

To avoid data loss in cases of temporary peak loads on system buses, the DMA FIFOs OPFs have significant local FIFOs. The width of the FIFO varies with the `PVP_OPFx_CTL.OSIZE` bit field settings. The individual OPFs have different FIFO depths:

- OPF0: 380 entries x 32 bits or 960 x 16 bits or 1920 x 8 bits
- OPF1: 1024 entries x 32 bits or 2048 x 16 bits or 4196 x 8 bits

- OPF2: 512 entries x 32 bits or 1024 x16 bits or 2048 x 8 bits
- OPF3: 32 entries x 32 bits or 64 x 16 bits or 128 x 8 bits

Therefore, it is important to assign OPF1 to the camera pipeline with the highest output data rate. For example, 32-bit results that come out of the CNVx, ACU or IIMx blocks, running at full input frame resolution, are better routed to OPF1. Output formatter 0 should be used for the camera pipe with the least output data rate. Typical candidates are items that are subject to data reduction (windowing, sub sampling, run-length encoding) or items that have small data widths (threshold index, edge classes). Output formatter 2 is designed for normal data rates. Unexpected overflows are reported by the OPF00VF, OPF10VF and OPF10VF status bits in the PVP\_STAT and PV00\_ILAT registers.

Output formatter 3 has a relatively small FIFO because the memory pipe has been designed to never overflow.

OPFs support the finish signaling to the DMA. This is described in detail later in the section [Finish Commands](#).

## Threshold-Histogram-Compression (THCx)

The PVP features two threshold-histogram-compression blocks. These blocks implement a collection of statistical and range reduction signal processing functions. The input to the THC blocks can be one of the following described in the following table and Figure 5 gives the detailed overview of the THC block

**Table 30-12:** THCx Block Connectivity

| Input 0 |         | Input 1 |      | Output 0 | Output 1 | Output 2 |
|---------|---------|---------|------|----------|----------|----------|
| s32     |         |         |      | s32      |          |          |
| Block   | Port    | Block   | Port |          |          |          |
| IPF0    | 0,1, 2  | n/a     | n/a  | result   | n/a      | n/a      |
| IPF1    | 0, 1, 2 |         |      |          |          |          |
| PMA     | 1, 2    |         |      |          |          |          |
| CNV0    | 0       |         |      |          |          |          |
| CNV1    | 0       |         |      |          |          |          |
| CNV2    | 0       |         |      |          |          |          |
| CNV3    | 0       |         |      |          |          |          |
| ACU     | 0       |         |      |          |          |          |
| PEC     | 2       |         |      |          |          |          |

**Figure 30-5:** Threshold Histogram Compression Block Diagram

The `PVP_THCx_CTL.ZEXT` bit determines how the input data is handled. When set to 1, the lower 16-bits of input data are zero extended to 32-bits and used for further processing. The upper 16-bits are used as an angle input. When the bit is cleared ( $= 0$ ), the entire 32-bits of input data are used for further processing. The angle input is set to 0.

The three stages of THC block operation are as follows.

- Threshold Unit
- Histogram Unit
- Compression Unit

The details of each unit are described in the sections that follow.

The threshold unit operates on the incoming pixels for the THC block. The output of the threshold unit is a 32-bit pixel out value and a 4-bit index value.

- **Clipping Mode** — In this mode the input pixel is classified in one of the three ranges. The input data is first compared to the value in the PVP\_THCx\_CMINTH register. If this value less than the value programmed in the register then the pixel out value is the PVP\_THCx\_CMINVAL register value and the index output is 0x0. If the input data is greater than the value programmed in the PVP\_THCx\_CMAXTH register, then the pixel out value is the PVP\_THCx\_CMAXVAL value and the index output is 0x2. If the input data lies between the two values the pixel out value is equal to the input data and the index output is 0x1.
- **Quantization Mode** — In this mode the input pixels are compared to the 16 PVP\_THCx\_THy registers and classified as belonging to one of sixteen bins. The registers must be programmed in ascending order from PVP\_THCx\_TH0 to PVP\_THCx\_TH15. The pixel out takes one of these 16 threshold values

based on floor logic. If the input is less than PVP\_THCx\_TH0, then the pixel out is the highest threshold value among the 16 threshold values. The index output is the number of the threshold register that the pixel out takes.

- **Hysteresis Mode** — In this mode the 16 PVP\_THCx\_THy registers are interpreted as eight pairs of threshold values starting from (TH0–TH1), (TH2–TH3), and so on. The register pairs form a range. If the input pixel value falls in this range then the pixel out depends on the previous output. The pixel out is the higher register in one of the eight pairs of threshold registers. The index output is the number of the threshold register pair that the pixel out takes.

The next figure shows example hysteresis functionality. The rounded numbers are index output when the input pixel falls in that region.

**Figure 30-7:** Hysteresis Example

If the pixel value falls in the gray region, the output index is computed based on the pseudo code below:

```
index = upper_bin
else if (previous_bin = lower_bin)
index = lower_bin
```

```
else if (previous_bin > upper_bin)
index = upper_bin
else
index = lower_bin
```

## Histogram Unit

The histogram unit has 16 histogram counters, each corresponding to one index. The counters run for the number of frames programmed in the PVP\_THCx\_HFCNT register. After the programmed number of frames the histogram counters are cleared and restarted. The histogram counters are moved to the PVP\_THCx\_HCNTy\_STAT registers at every frame. The value of the current frame count is also available in the PVP\_THCx\_HFCNT\_STAT register.

When the threshold unit is operating in hysteresis mode, the index output ranges from 0 to 7 and therefore only the PVP\_THCx\_HCNT0\_STAT to PVP\_THCx\_HCNT7\_STAT registers contain valid data. When the threshold unit is operating in clipping mode, the index output ranges from 0 to 2 and only the PVP\_THCx\_HCNT0\_STAT to PVP\_THCx\_HCNT2\_STAT registers have valid data. Each of the histogram counters is 32 bits wide. If the counter reaches the highest value of 0xFFFFFFFF before the expiration of the value in the PVP\_THCx\_HFCNT register, then the counter does not overflow but saturates at that value.

The histogram unit can be enabled or disabled using the PVP\_THCx\_CTL.HISTEN bit.

## Compression Unit

The compression unit uses the run-length-encoding (RLE) technique to compress data. In most cases the output from the threshold unit has a lot of repetition and converting the sequence of data values into a report containing value and run-length count reduces throughput at the output of the THC block.

The value and run-length are grouped into a single word based on the PVP\_THCx\_CTL.0FRMT bits. The run-length indicates the actual number of pixels and not repetitions, so the minimum run-length value is 1.

If the PVP\_THCx\_CTL.RLEFRAME bit is 0 then a report is generated at the end of a row and the run-length counter is reset. If = 1, then compression works across rows in the frame. Due to the nature of compression, a variable number of reports are generated per row or per frame. The PVP\_THCx\_RREP\_STAT register contains the actual number of reports generated per frame. A value can be set in the PVP\_THCx\_RMAXREP register to limit the number of reports generated per row or per frame. When the number of reports reaches the limit then the last report's run-length field is cleared.

Note that some formats in PVP\_THCx\_CTL.0FRMT bits disables compression. Also, some formats use angle information to generate the final report.

A typical usage of compression unit is by setting the maximum number of reports in PVP\_THCx\_RMAXREP register. Program the output DMA to transfer the maximum number of reports. Once all the reports are generated for the frame, the compression unit sends a *Finish Command* to DMA, ensuring that the work unit moves to the next work unit despite the variable data per work unit. The actual number of reports generated can be read from PVP\_THCx\_RREP\_STAT status register.

## Windowing

The histogram and compression units support windowing to filter incoming pixels.

The histogram window supports filtering pixels either inside or outside the window. The window mode is selected by setting the `PVP_THCx_CTL.HISTWM` bits. The window coordinates are specified by the `PVP_THCx_HHPOS`, `PVP_THCx_HVPOS`, `PVP_THCx_HHCNT` and `PVP_THCx_HVCNT` registers.

The compression window supports filtering pixels only inside the window. The window mode is selected by setting the `PVP_THCx_CTL.RLEWM` bits. The window coordinates are specified by the `PVP_THCx_RHPOS`, `PVP_THCx_RVPOS`, `PVP_THCx_RHCNT` and `PVP_THCx_RVCNT` registers. The minimum supported window size is 16x16.

**Figure 30-8:** Definition of RLE and Histogram Windows

## Convolution (CNVx)

Convolution is a mathematical operation on two signals producing a third signal which is typically viewed as a modified version of one of the original signals. The PVP has four convolution blocks.

The convolution block implements a 2D convolution of the input pixels with a 5x5 coefficient matrix. The actual mathematical operation is described in the equation below.

$$Y_{i,j} \Big|_{i=0-(M-1), j=0-(N-1)} = \sum_{m=0-4, n=0-4} X_{i+m-2, j+n-2} * C_{m,n}$$

where:

- N = number of columns in the input data
- M = number of rows in the input data
- Y = MxN output data
- X = MxN input data
- C = 5x5 coefficient data

Note that the strict mathematical formula for convolution mirrors the coefficients in both directions before the MAC operation. For CNV blocks, the coefficients are multiplied in place to simplify the operation (similar to Correlation). Programs can always put the 5x5 coefficients in different order to realize either convolution or correlation.

The following figure shows the data flow within the CNV block.

**Figure 30-9:** CNVx Overview

Figure 30-10: Convolution Block Connectivity

Table 30-13: CNV0 Block Connectivity

| Input 0 |         | Input 1 |      | Output 0 | Output 1 | Output 2 |
|---------|---------|---------|------|----------|----------|----------|

| CNV1    | 0       |         |      |          |          |          |
| CNV3    | 0       |         |      |          |          |          |

**Table 30-16:** CNV3 Block Connectivity

| Input 0 |         | Input 1 |      | Output 0 | Output 1 | Output 2 |
|---------|---------|---------|------|----------|----------|----------|
| s16     |         |         |      | s32      |          |          |
| Block   | Port    | Block   | Port |          |          |          |
| IPF0    | 0, 1, 2 | n/a     | n/a  | Result   | n/a      | n/a      |
| IPF1    | 0, 1, 2 |         |      |          |          |          |
| CNV0    | 0       |         |      |          |          |          |
| CNV1    | 0       |         |      |          |          |          |
| CNV2    | 0       |         |      |          |          |          |

The CNV block expects 16-bit signed input data and drives 32-bit signed output data. The key features of the block are:

- When the `PVP_CNVx_CTL.SAT32` bit = 0, the output is saturated to a 16-bit value and sign extended to drive the 32-bit output. When the bit = 1, the output is saturated to a 32-bit value.
- The boundary pixels at the output require input pixels beyond the edges for computation. When the `PVP_CNVx_CTL.ZEROFILL` bit = 1, the input pixels outside the edges are considered to be 0. When the bit = 0, the edges are duplicated beyond the boundary of the input pixels.
- The `PVP_CNVx_CTL.SHIFT` bit controls output arithmetic right shift from 0 to 31 bits. This allows the coefficients to be in fractional format with full control of the placement of the binary point.
- The CNV block supports downscaling by dropping output pixels in both directions. The `PVP_CNVx_SCALE.HSCL` bits are used to set the horizontal downscale factor and `PVP_CNVx_SCALE.VSCL` bits are used to set the vertical downscale factor. The block supports decimation in powers of 2. The maximum horizontal downscale factor is 1024 and the vertical factor is 512.

The value programmed in these registers is one less than the actual scale factor. Therefore a scale factor of 0 disables downscaling.

The `PVP_CNVx_SCALE.HSCL` and `PVP_CNVx_SCALE.VSCL` settings must not change on the fly if the output of the downscaling CNVx block supplies another CNVx block. If so, the `DRAIN` bit must be set for the new configuration.

- The CNV block supports 5x5 convolution kernels. The block automatically supports any smaller 2D kernels like 3x3 by centering the kernel in the 5x5 matrix and filling the surrounding values with zeros. The coefficients for the  $y^{\text{th}}$  row are set in the `PVP_CNVx_Cy0Cy1`, `PVP_CNVx_Cy2Cy3` and `PVP_CNVx_Cy4` registers.
- The accumulator in the CNV block is 37-bits wide—no overflow is possible during MAC operations.

**NOTE:** A downscaled CNV cannot drive another CNV. A CNV can only drive another CNV as long as it is not downscaled.

## Polar Magnitude and Angle Block (PMAx)

The PVP features one polar magnitude and angle block (PMA). The block takes two 16-bit signed inputs as coordinates in the Cartesian form (x, y) and converts them into Polar form (Magnitude, Angle  $\phi$ ).

**Figure 30-11:** Cartesian vs. Polar form

The PMA block applies two different mathematical formulas (Pythagorean) to obtain magnitude and angle:

$$\text{Magnitude} = \sqrt{|x|^2 + |y|^2}$$

$$\phi = \arctan\left(\frac{y}{x}\right)$$

**Figure 30-12:** PMA Equations

The magnitude is output as a 16-bit unsigned value, ranging from 0 to the square root of 2. For  $x = y = 0x7FFF$ , it outputs `0xB503`. For the special case of  $x = y = 0x8000$ , the PMA outputs `0xB504`.

The angle  $\phi$  is calculated to five bits of resolution ( $11.25^\circ$ ) and an accuracy of  $\pm 0.25^\circ$ . Mathematically, the angle is a signed value. However, since the angle is always zero-extended when output to 16-bit or 32-bit buses, it can also be interpreted as an unsigned binning value.

**Figure 30-13:** PMA Angle Binning

The PMA sets the angle to 0x08 ( $+90^\circ$ ) if the x input value is 0 and the y input is a positive value and to 0x18 ( $-90^\circ$ ) if the y input is negative. If both, x and y are zero, the PMA outputs 0x1F by convention.

Other than data flow configuration, the PMA block does not have any control or status registers. Both of its inputs can be individually configured to receive data from any of the convolution blocks or from either input formatter. Care is required in that both inputs are timed consistently and are not subject to non-matching latency in up front pipeline configuration.

**Table 30-17:** PMA Block Connectivity

| Input 0 | Block | Port    | Input 1 | Block | Port    | Output                                                             |
|---------|-------|---------|---------|-------|---------|--------------------------------------------------------------------|
| s16     | IPF0  | 0, 1, 2 | s16     | IPF0  | 0, 1, 2 | Port1: s32<br>magnitude<br>Port1: s32<br>angle Port2:<br>s32 combo |
|         | IPF1  | 0, 1, 2 |         | IPF1  | 0, 1, 2 |                                                                    |
|         | CNV0  | 0       |         | CNV0  | 0       |                                                                    |
|         | CNV1  | 0       |         | CNV1  | 0       |                                                                    |
|         | CNV2  | 0       |         | CNV2  | 0       |                                                                    |
|         | CNV3  | 0       |         | CNV3  | 0       |                                                                    |

**Figure 30-14:** PMA Connectivity

The PMA block has three output ports. If PMA is enabled, all three 32-bit ports are always active as follows.

- Port 0 drives the 16-bit unsigned magnitude. The upper 16 bits are always driven as zeros.
- Port 1 drives the 5-bit angle value. The upper 27 bits are always driven as zeros.
- Port 2 drives a combined format. The lower 16 bits contain the magnitude, bits 16 to 20 drive the angle, and the upper ones are always zero. The Port 2 signal is not only good for being streamed to system memory. The THCx blocks have special functionality to deal with this format.

## Arithmetic Control Unit (ACUx)

The PVP features one arithmetic control unit (ACU). It provides basic 32-bit math like addition, subtraction, multiplication and division. It also features a 48-bit accumulator and can normalize and saturate on the output. While the ACU is important building block in many video applications, it also adds significant general-purpose value to the processor.

The ACU block has two 32-bit inputs (x, y) and one 32-bit output (res). It features a number of registers that hold constant operands. The *offset* value can be used for addition and subtraction. The *factor* value can be used for multiplication and division. The *shift* value is used for normalization and the *min* and *max* pair of registers control the saturation.

As shown in figure below, the individual operation can also be combined. Multiple computes can be performed in a single pass. For example,  $((x+y) \times 3) \gg 2$  can be performed by setting FACTOR = 3 and SHIFT = 2.

ACU Overview

For combinations of computes the individual operations need to be in the order shown above. For example  $((x \gg 2) \times 3) + y$  cannot be performed in a single pass. Similarly, not every operation can be done on every operand. The following table illustrates options available by individual math sub blocks.

**Table 30-18:** ACU Block Operations and Operands

| RESULT | OPERATIONS                                          | OPERANDS                                                         |
|--------|-----------------------------------------------------|------------------------------------------------------------------|
| SUM =  | + (32-bit signed add)<br>- (32-bit signed subtract) | X, Y<br>Y, X<br>X, OFFSET<br>OFFSET, X<br>Y, OFFSET<br>OFFSET, Y |

**Table 30-18:** ACU Block Operations and Operands (Continued)

| RESULT | OPERATIONS                                                                         | OPERANDS                                                                                       |
|--------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|

| NORM = | 48-bit arithmetic right shift                                                      | X, SHIFT<br>SUM, SHIFT<br>PROD, SHIFT<br>ACC, SHIFT                                            |
| RES =  | 32-bit signed saturation                                                           | NORM, MIN, MAX                                                                                 |

**Figure 30-15: ACU Connectivity**

For divide-by-zero operations, the quotient is set to the enumerator's value. The remainder is set to zero. The event is reported by the `PVP_STAT.ACUDIVERR` status bit. The operation itself progresses normally.

The intermediate results SUM and PROD are 32-bit values. If the result exceeds 32-bit range, the data is implicitly saturated to `0x7FFFFFFF` for positive results and to `0x80000000` for negative results. The `PVP_STAT.ACUSUMSAT` and `PVP_STAT.ACUPRODSAT` status bits report the saturation events.

If accumulation is active (`PVP_ACU0_CTL.SFTINP = 3`), the ACU outputs only one value every video row (`PVP_ACU0_CTL.ACCFRAME = 0`) or every frame (`PVP_ACU0_CTL.ACCFRAME = 1`). With every new row or frame, the accumulator is cleared automatically. The 32-bit input values or the intermediate 32-bit SUM or PROD results are summed up into the 48-bit accumulator. If intermediate accumulation results exceed

48 bits before the end of row/frame the accumulator silently overflows. It neither saturates nor generates a status event.

The SHIFT and the SAT operations are not optional. Their functionality can be bypassed by leaving the default zero value in the PVP\_ACU0\_SHIFT register (no shift) and by setting the clipping values in the PVP\_ACU0\_MIN register to 0x80000000 and in the PVP\_ACU0\_MAX register to 0x7FFFFFFF. Saturation events due to MAX/MIN register method are reported by the PVP\_STAT.ACU0OUTSAT status bit.

The ACU can receive data from either input formatter or any convolution block. Both inputs can be individually configured. Care is required to properly time input data so that both inputs match.

**Table 30-19:** ACU Block Connectivity

| Input 0 | Block | Port    | Input 1 | Block | Port    | Output |
|---------|-------|---------|---------|-------|---------|--------|
| s32     | IPF0  | 0, 1, 2 | s32     | IPF0  | 0, 1, 2 | s32    |
|         | IPF1  | 0, 1, 2 |         | IPF1  | 0, 1, 2 |        |
|         | CNV0  | 0       |         | CNV0  | 0       |        |
|         | CNV1  | 0       |         | CNV1  | 0       |        |
|         | CNV2  | 0       |         | CNV2  | 0       |        |
|         | CNV3  | 0       |         | CNV3  | 0       |        |

If the X input doesn't influence the ACU output based on the PVP\_ACU\_CTL settings, then the PVP\_ACU\_CFG.IBLOCK0 bit must be set to zero. Similarly, if Y is not used in the equation, the PVP\_ACU\_CFG.IBLOCK1 bit must be zero.

Input values can be doubled using the adder, if X and Y inputs sense that same data. Similarly, input values can be squared. The intermediate SUM result, however, cannot be squared.

The ACU is very useful in memory pipe mode when the supported operation needs to apply to all elements in an array. If one operand is a constant value as in  $res_i = x_i \% c$ , then the constant  $c$  value is best written into the constant register, (the PVP\_ACU\_FACTOR register in the example). Input 0 ( $x$ ) is typically connected to port 0 of IPF1. If, however, the operation is applied to elements of two arrays as in  $res_i = x_i / y_i$ , then, input 0 ( $x$ ) typically connects to port 1 of IPF1 and input 1 ( $y$ ) connects to port 2. The IPF expects the input data in interleaved manner, ( $x_0, y_0, x_1, y_1, x_2, y_2, \dots$ ). If data is not already stored this way in memory, the 2-dimensional feature of the DMA can perform the interleaving.

## Pixel Edge Classifier (PEC)

The PEC block processes the edge information to enhance the features for further vision processing. The PEC supports two modes of operation—1st derivative mode or PEC-1 and 2nd derivative mode or PEC-2. These modes are mutually exclusive and the PEC can operate in only one mode at a time. The PEC block takes 32-bit input data and drive up to three streams of output data.

PEC-1 supports the subsequent stages after the Sobel filters for the first derivative Canny edge detection algorithm. The primary features of PEC-1 are:

- Edge thinning feature using non-maximum suppression.
- Streaking elimination using hysteresis (3-level thresholding on the magnitude of the gradient).

In PEC-1 mode, the block expects the magnitude on the lower 16-bits and the angle information on the upper 16-bits. Therefore, the PEC block can either interface to the PMA output port-2 which has the packed magnitude and angle, or the IPF ports, assuming the IPF drives the packed magnitude, angle data.

The PEC-2 can generate 8-connected chain codes for contour tracing using output from second derivative edge detection methods like Difference of Gaussian (DoG) and Laplacian of Gaussian (LoG). The primary features of PEC-2 are:

- Detection of zero-crossing points in the second derivative filter output.
- Classification of the edges based on the edge direction.
- Compute location of the edge with half pixel resolution (sub-pixel interpolation).
- The PEC block supports back-to-back frame size change in output from CNV block. The block supports incoming frames with a decimation ratio of up to 256 (1, 2, 4, 8, 16, 32, 64, 128 and 256). The smallest frame size that the PEC can support is 16x16.
- Both PEC-1 and PEC-2 output zeros for pixels on the frame boundaries.
- The PEC only supports even sized frames.
- The PEC mode cannot change from frame to frame. The block has to be disabled and enabled to change mode.

In PEC-2 mode, the block expects 16-bit signed input data. Therefore, the PEC block can interface with either the IPF ports, the ACU block (32-bit signed, but saturated to 16-bits) or any of the CNV blocks (32-bit signed, but saturated to 16-bits). In this mode the PEC only operates on the lower 16 bits of the 32-bit signed input. Figure x shows the high level connectivity of the PEC block.

Figure 30-16: Pixel Edge Classifier Block Connectivity

The details of the connectivity of the PEC block are described in the table below.

Table 30-20: PEC Block Connectivity

| Input 0 |         | Input 1 |      | Output 0       | Output 1       | Output 2          |
|---------|---------|---------|------|----------------|----------------|-------------------|
| s32     |         |         |      | u8             | u32            | u32               |
| Block   | Port    | Block   | Port |                |                |                   |
| IPF0    | 0, 1, 2 | n/a     | n/a  | encoded result | decoded result | angle only result |
| IPF1    | 0, 1, 2 |         |      |                |                |                   |
| PMA     | 2       |         |      |                |                |                   |
| CNV0    | 0       |         |      |                |                |                   |
| CNV1    | 0       |         |      |                |                |                   |
| CNV2    | 0       |         |      |                |                |                   |
| CNV3    | 0       |         |      |                |                |                   |
| ACU     | 0       |         |      |                |                |                   |

## PEC 1st Derivative Mode (PEC-1)

This mode is selected by setting the `PVP_PEC_CTL.MODE` bit to 0 and works on 16-bit gradient magnitude and 5-bit gradient angle from the PMA block.

### Angle Mapping

The angle is rounded to one of four angles representing vertical, horizontal and the two diagonals. The 5-bit angle bin output of the PMA is mapped to the four directions as shown in the following figure.

**Figure 30-17:** PMA Angle Bin Mapping to PEC-1 Angle

### Non-Maximum Suppression

A search is performed with the input magnitude gradient to determine if the magnitude assumes a local maximum in the gradient direction so that thin edges are produced. This is referred to as *Non-Maximum Suppression*.

The PEC-1 works on the 3x3 window with the center pixel as the pixel of interest and computes whether the pixel is a local maximum or not. Consider a 3x3 window of magnitude gradients as shown below.

|     |     |     |
|-----|-----|-----|
| P11 | P12 | P13 |
| P21 | P22 | P23 |
| P31 | P32 | P33 |

The pixel of interest (P22) is *maxima* (M),

- If the rounded angle is 0 degrees and if its intensity is greater than the intensity in the west (P21) and greater than the intensity in the east, (P23) directions.
- If the rounded angle is 90 degrees and if its intensity is greater than the intensity in the north (P12) and greater than the intensity in the south (P32) directions.
- If the rounded angle is 135 degrees and if its intensity is greater than the intensity in the north west (P11) and greater than the intensity in the south east (P33) directions.
- If the rounded angle is 45 degrees and if its intensity is greater than the intensity in the north east (P13) and greater than the intensity in the south west (P31) directions.

In cases where the gradient magnitude is the same for more than one pixel along the gradient direction “equality” (E) information is also provided by PEC-1. Edge-tracing software uses M and E to find the exact location of the edge. Consider the same 3x3 window as before.

The pixel of interest (P22) is *equality* (E),

- If the rounded angle is zero degrees and if its intensity is greater than or equal to the intensity in the west (P21) and greater than or equal to the intensity in the east, (P23) directions.
- If the rounded angle is 90 degrees and if its intensity is greater than or equal to the intensity in the north (P12) and greater than or equal to the intensity in the south (P32) directions.
- If the rounded angle is 135 degrees and if its intensity is greater than or equal to the intensity in the north west (P11) and greater than or equal to the intensity in the south east (P33) directions.
- If the rounded angle is 45 degrees and if its intensity is greater than or equal to the intensity in the north east (P13) and greater than or equal to the intensity in the south west (P31) directions.

## Hysteresis Thresholding

The Canny algorithm uses *hysteresis* thresholding. When a single threshold value is used, the fluctuations of the gradient magnitude (due to noise) above and below the threshold value results in pixels being classified as edges and non-edges. In such cases the edge line appears broken. This phenomenon is commonly referred to as streaking. PEC-1 eliminates streaking by comparing the magnitude against two threshold registers, PVP\_PEC\_D1TH0 and PVP\_PEC\_D1TH1.

If the magnitude lies below PVP\_PEC\_D1TH0 (TL), then the pixel is called *no edge*. If the magnitude lies above PVP\_PEC\_D1TH1 (TH) then the pixel is termed as *strong edge*. If it lies between TL and TH, then the pixel is termed as *weak edge*. The post-processing software can connect the weak edge to strong edge to create a unbroken edge line. Note that TH must be programmed higher than TL for hysteresis.

## Output Format

The PEC-1 produces three different outputs on three ports. The details are described below.

## Port0

This output is primarily used for post-processing in software. Encoded 8-bit output is produced for every input pixel as shown below.

| bit 7     | bit 6 | bit 5 | bit 4 | bit 3 | bit 2 | bit 1 | bit 0 |
|-----------|-------|-------|-------|-------|-------|-------|-------|
| Angle Bin |       |       |       |       | Code  |       |       |

The 5-bit angle bin from the PMA/IPF is passed on to the 5 MSBs of the PEC-1 output if the pixel magnitude is greater than or equal to TL. If the pixel magnitude is less than TL, the 5 MSBs are suppressed to zeros. PEC-1 combines the maxima (M), equality (E) and hysteresis thresholding to produce a 3-bit code output (which forms the 3 LSBs of the PEC-1 output) whose bits are defined as shown below.]

**Table 30-21:** PEC-1 Code Mapping

| LSB of PEC Output | Description                   |
|-------------------|-------------------------------|
| 000               | mag < TL                      |
| 001               | mag >= TL, mag < TH, M=0, E=0 |
| 010               | mag >= TL, mag < TH, M=0, E=1 |
| 011               | mag >= TL, mag < TH, M=1, E=1 |
| 100               | reserved                      |
| 101               | mag >= TH, M=0, E=0           |
| 110               | mag >= TH, M=0, E=1           |
| 111               | mag >= TH, M=1, E=1           |

## Port1

This output is 32 bits wide and is used primarily for the IIM block to accumulate the edge statistics. The output can be either 8-bit bin size encoded or 16-bit bin size encoded based on the setting of the PVP\_PEC\_CTL.OSIZE control bit. If bit is 0 (indicating 8-bit bin size), the 32-bit output represents four angle bins, each having a strong/weak edge information as shown in the table below.

**Table 30-22:** Output Encoding for 8-bit Bin Size

| Angle    | Edge    | Encoding                            |
|----------|---------|-------------------------------------|
| Mag < TL | No edge | 00000000 00000000 00000000 00000000 |

**Table 30-22:** Output Encoding for 8-bit Bin Size (Continued)

| Angle        | Edge   | Encoding                            |
|--------------|--------|-------------------------------------|
| 0° or 180°   | Weak   | 00000000 00000000 00000000 00000001 |
| 0° or 180°   | Strong | 00000000 00000000 00000000 00000010 |
| 45° or 225°  | Weak   | 00000000 00000000 00000001 00000000 |
| 45° or 225°  | Strong | 00000000 00000000 00000010 00000000 |
| 90° or 270°  | Weak   | 00000000 00000001 00000000 00000000 |
| 90° or 270°  | Strong | 00000000 00000010 00000000 00000000 |
| 135° or 315° | Weak   | 00000001 00000000 00000000 00000000 |
| 135° or 315° | Strong | 00000010 00000000 00000000 00000000 |

If the PVP\_PEC\_CTL.0SIZE bit is 1 (indicating 16-bit bin size), the 32-bit output represents two angle bins, each having a strong/weak edge information as shown in the table below.

**Table 30-23:** Output Encoding for 16-bit Bin Size

| Angle                       | Edge    | Encoding                            |
|-----------------------------|---------|-------------------------------------|
| Mag < TL                    | No edge | 00000000 00000000 00000000 00000000 |
| 0° or 180° or 90° or 270°   | Weak    | 00000000 00000000 00000000 00000001 |
| 0° or 180° or 90° or 270°   | Strong  | 00000000 00000000 00000000 00000010 |
| 45° or 225° or 135° or 315° | Weak    | 00000000 00000001 00000000 00000000 |
| 45° or 225° or 135° or 315° | Strong  | 00000000 00000010 00000000 00000000 |

The strong/weak edge is determined by the threshold values programmed in the PVP\_PEC\_D1TH0 (TL) and PVP\_PEC\_D1TH1 (TH) registers. The PVP\_PEC\_CTL.IGNTH1 bit supports masking the differences between strong and weak edges. If this bit is 0, weak and strong edges are treated differently and the output is as per the tables above. If this bit is 1, all the edges are considered weak irrespective of the TH value and the output is encoded to represent a weak edge as per the above tables.

## Port2

This output is 5 bits wide and is used primarily for generating the angle histograms. The 5-bit angle bin from the PMA/IPF is passed on to this port if the pixel magnitude is greater than or equal to the

PVP\_PEC\_D1TH0 register. If the center pixel magnitude is less than PVP\_PEC\_D1TH0, this output is suppressed to zeros.

## PEC 2nd Derivative Mode (PEC-2)

This mode is selected by setting the PVP\_PEC\_CTL.MODE bit to 1. PEC-2 works on 16-bit signed data from the second derivative filter output like DoG and LoG. The primary functions in this mode follow.

### Zero-Crossing Detection

Edges lie on the zero crossing points (-ve to +ve and +ve to -ve transition points) in the 2nd derivative filter output. The PEC-2 scans through the filtered image and determines zero crossings in horizontal (zH) and vertical (zV) directions and assigns pre-defined 3-bit zero crossing codes. The zero crossing detection algorithm is explained below.

Whenever there is a +ve to -ve or -ve to +ve in the filtered image, the pixel with +ve value in the image is considered to be a valid zero-crossing point. As the 2nd derivative filtered image is more prone to errors due to noise, a user defined threshold is used to remove the noise during zero crossing detection. Zero crossings are considered valid only if there is a sign change and the difference between the 2nd derivative values of these two pixels is greater than the threshold in the PVP\_PEC\_D2TH0 register. When the pixel of interest is has a value of zero, then it is considered as a valid zero-crossing point if the two pixels on the left and right (for horizontal and top, bottom for vertical) are values with opposite signs, (+ 0 -) or (- 0 +). The MSB of the 3-bit code is set if the difference between the pixels is greater than the threshold in the PVP\_PEC\_D2\_TH1 register.

The following table shows the different combinations of 2nd derivative image values for the pixel of interest, the pixel on the left and the pixel on the right and the corresponding 3-bit zero-crossing codes for horizontal direction (zH). The vertical zero-crossings (zV) are obtained by replacing left pixel with the top pixel and the right pixel with the bottom pixel in the same table.

**Table 30-24:** Zero Crossing Codes

| Left       | Center | Right      | Computation                                                                                                                   | zH (3-bit)        |
|------------|--------|------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Don't care | -ve    | Don't care |                                                                                                                               | 000               |
| +ve / 0    | +ve    | +ve / 0    |                                                                                                                               | 000               |
| -ve / 0    | 0      | 0 / -ve    |                                                                                                                               | 000               |

## Sub-Pixel Interpolation

A linear interpolation of the filtered image at the zero crossings is performed to determine a more precise location of the zero crossings. The values of (left, center, right) for horizontal direction and (top, center,

bottom) for vertical direction are compared for relative differences. Additionally, edge location with half pixel resolution is computed.

Table 19 explains the different zero crossing codes, pixel value sequences and the corresponding sub-pixel values (HSub, 2-bits). The vertical sub-pixel values (VSub, 2-bits) can be computed using the same procedure, replacing left pixel with top pixel, right pixel with bottom pixel and the 2 LSBs of zH with zV.

**Table 30-25:** Sub-Pixel Computation

| zH (2-bits) | Left       | Center     | Right      | Computation                   | Sub-pixel<br>HSub (2-bits) |
|-------------|------------|------------|------------|-------------------------------|----------------------------|

## Angle Classification

The 2nd derivative filtering of an image doesn't convey any information about the orientation of the edges in the image. The angle classification unit in PEC-2 extracts the angle information of the edges from the zero crossing codes of pixels in the 3x3 neighborhood. The classifier uses only the two lower bits of zH and zV, (both weak and strong zero crossings). The classifier classifies the edges into eight basic directions (0°, 45°, 90°, 135°, 180°, 225°, 270° and 315°) if the PVP\_PEC\_CTL.ZCRSS bit is 0. The classifier outputs a 4-bit angle index as described in the table below.

**Table 30-26:** Angle Classification

| Priority | Zero Crossing Code Combination                                                         | Class          | Angle Index (4-bit) |
|----------|----------------------------------------------------------------------------------------|----------------|---------------------|
| 1        | $zH(r,c) = 00 \ \& \ zV(r,c) = 00$                                                     | no edge        | 0000                |
| 2        | Not matching any of the combination 4 to 11.                                           | no match       | 0001                |
| 3        | Matching more than one combination in 4 to 11.                                         | multiple match | 0010                |
| 4        | $zV(r,c) = 01 \ \& \ zV(r,c+1) = 01$                                                   | 0°             | 1000                |
| 5        | $(zH(r,c) = 01 \    \ zV(r,c) = 01) \ \& \ (zH(r-1,c+1) = 01 \    \ zV(r-1,c+1) = 01)$ | 45°            | 1001                |
| 6        | $zH(r,c) = 01 \ \& \ zH(r-1,c) = 01$                                                   | 90°            | 1010                |

**Table 30-26:** Angle Classification (Continued)

| Priority | Zero Crossing Code Combination                                                                | Class | Angle Index (4-bit) |
|----------|-----------------------------------------------------------------------------------------------|-------|---------------------|
| 7        | $u$<br>$(zH(r-1,c-1) = 01 \parallel zV(r-1,c-1) = 10)$                                        | 135°  | 1011                |
| 8        | $zV(r,c) = 10 \& zV(r,c-1) = 10$                                                              | 180°  | 1100                |
| 9        | $(zH(r,c) = 10 \parallel zV(r,c) = 10) \&$<br>$(zH(r+1,c-1) = 10 \parallel zV(r+1,c-1) = 10)$ | 225°  | 1101                |
| 10       | $zH(r,c) = 10 \& zH(r+1,c) = 10$                                                              | 270°  | 1110                |
| 11       | $(zH(r,c) = 10 \parallel zV(r,c) = 01) \&$<br>$(zH(r+1,c+1) = 10 \parallel zV(r+1,c+1) = 01)$ | 315°  | 1111                |

The angle index generated above is considered a strong edge only if all the involved zH or zV values used in the computation are strong (or have their MSB = 1). If the PVP\_PEC\_CTL.IGNTH1 bit is set then the strong/weak zero-crossing information (MSB of zH and zV) is ignored by the classifier.

## Output Format

The PEC-2 produces three different outputs on three ports as described below.

Port0

This output is used primarily for post-processing in software. The 8-bit encoded output is produced for every input pixel as shown below.

| PVP_PEC_CTL.ZCRS | bit 7 | bit 6 | bit 5 | bit 4 | bit 3       | bit 2 | bit 1 | bit 0 |
|------------------|-------|-------|-------|-------|-------------|-------|-------|-------|
| 0                | VSub  |       | HSub  |       | Angle Index |       |       |       |
| 1                | VSub  |       | HSub  |       | zV          |       | zH    |       |

Port1

This output is 32-bits wide and is used primarily for the IIM block to accumulate the edge statistics. The output is not valid when the PVP\_PEC\_CTL.ZCRSS bit = 1 since the edges are not classified in this mode. PEC-2 produces a 32-bit output which is exactly similar to the output generated by PEC-1. The angle is computed as shown in the [Angle Classification](#) table. For priority 1, 2, and 3, the output is considered as no edge and all zeros are driven on the port.

Port2

This output is 5-bits wide and is used primarily for the THCx block to generate the angle histograms. PEC-2 drives the 4-bit angle index described in the [Angle Classification](#) table. Zero is driven on the MSB of the 5-bit port. For priority 1, 2, and 3, the output is considered as no edge and all zeros are driven on the port. The output is not valid when the PVP\_PEC\_CTL.ZCRSS bit = 1 since the edges are not classified in this mode.

## Integral Image Block (IIMx)

The PVP features two integral image blocks (IIM). The IIMs calculate a 2-dimensional integral over the input frame and outputs the summed area table (SAT). Alternatively, the IIM blocks can generate a rotated SAT (RSAT) or can integrate in horizontal dimension only (integral row mode). The operating mode is controlled by the PVP\_IIMx\_CTL.MODE bit field.

### Integral Row Mode

In integral row mode the IIM blocks accumulate the input values over video rows. Unlike the ACU's accumulation mode, integral row mode outputs the integral every pixel. For every input data  $Inp_{I,J}$  the IIM blocks output is as shown in the following equation.

$$IROW_{I,J} = \sum_{i=0}^{I-1} Inp_{i,J} \quad IROW_{I,J} = Inp_{I,J} + IROW_{I-1,J}$$

The initial value of the integral is assumed to be zero. Therefore,  $IROW_{0,J} = Inp_{0,J}$ . In the IROW output map, each value contains the accumulated input values from the respective row's origin to the actual position as shown in the following example.

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 2 | 0 | 1 | 1 | 0 | 2 | 3 | 0 |
| 0 | 0 | 1 | 0 | 3 | 0 | 0 | 0 |
| 0 | 2 | 3 | 1 | 0 | 1 | 0 | 0 |
| 0 | 0 | 1 | 2 | 0 | 1 | 0 | 5 |
| 1 | 0 | 0 | 1 | 0 | 0 | 2 | 0 |
| 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 |

Input Data:  
 $0+2+3+1+0+1+0 = 7$

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 2 | 2 | 3 | 4 | 4 | 6 | 9 | 9 |
| 0 | 0 | 1 | 1 | 4 | 4 | 4 | 4 |
| 0 | 2 | 5 | 6 | 6 | 7 | 7 | 7 |
| 0 | 0 | 1 | 3 | 3 | 4 | 4 | 9 |
| 1 | 1 | 1 | 2 | 2 | 2 | 4 | 4 |
| 1 | 1 | 2 | 2 | 2 | 3 | 4 | 4 |

Integral Row Mode

**Figure 30-18:** Illustration of Integral Row Mode

### Summed Area Table (SAT) Mode

In 2-dimensional SAT mode, the following equation is performed for every pixel.

$$SAT_{I,J} = \sum_{j=0}^{J-1} \sum_{i=0}^{I-1} Inp_{i,j} \quad SAT_{I,J} = Inp_{I,J} + SAT_{I-1,J} + SAT_{I,J-1} - SAT_{I-1,J-1}$$

Again, initial values of the integral are assumed to be zero— $SAT_{-1,J} = 0$  and  $SAT_{I,-1} = 0$ . In the SAT output map, each value contains the accumulated input values from the frame's origin to the actual position as shown in the figure below.

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 2 | 0 | 1 | 1 | 0 | 2 | 3 | 0 |
| 0 | 0 | 1 | 0 | 3 | 0 | 0 | 0 |
| 0 | 2 | 3 | 1 | 0 | 1 | 0 | 0 |
| 0 | 0 | 1 | 2 | 0 | 1 | 0 | 5 |
| 1 | 0 | 0 | 1 | 0 | 0 | 2 | 0 |
| 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 |

*Input Data:*  
 $2+0+1+1+0+0+1+0+0+2+3+1 = 11$

|   |   |    |    |    |    |    |    |
|---|---|----|----|----|----|----|----|
| 2 | 2 | 3  | 4  | 4  | 6  | 9  | 9  |
| 2 | 2 | 4  | 5  | 8  | 10 | 13 | 13 |
| 2 | 4 | 9  | 11 | 14 | 17 | 20 | 20 |
| 2 | 4 | 10 | 14 | 17 | 21 | 24 | 29 |
| 3 | 5 | 11 | 16 | 19 | 23 | 28 | 33 |
| 4 | 6 | 13 | 18 | 21 | 26 | 32 | 37 |

*SAT Mode*

**Figure 30-19:** Illustration of SAT Mode

## Rotated Summed Area Table (RSAT) Mode

In RSAT mode a  $-45^\circ$  rotated view is applied to the input coordinates. Each element of the RSAT output map contains the integral of all elements in the pyramid headed by the actual position. The IIM engine process according to the following procedure.

First Column:

$$RSAT_{0,J} = Inp_{0,J} + Inp_{0,J-1} + RSAT_{1,J-1}$$

Last Column:

$$RSAT_{I,J} = Inp_{I,J} + Inp_{I,J-1} + RSAT_{I-1,J-1}$$

All others:

$$RSAT_{I,J} = Inp_{I,J} + Inp_{I,J-1} + RSAT_{I+1,J-1} + RSAT_{I-1,J-1} - RSAT_{I,J-2}$$

All values outside of the region are defined as zero— $Inp_{I,-1} = RSAT_{I,-1} = RSAT_{I,-2} = 0$ .

**Figure 30-20:** Illustration of RSAT Mode

## Using SAT and RSAT Maps

The utility of the integral is not only that each position contains the sum of all input values between the actual position and the frame origin. It is that with only a small number of operations, post-processing software can determine the integral value of any rectangular region of the frame. For regular rectangles the SAT output can be used. For 45° rotated rectangles the RSAT output applies. This is illustrated in the following figure.

**Figure 30-21:** Using SAT Maps

Rather than summing up all original values of a rectangular region of the frame, software can perform simple math on the SAT output of the IIM blocks. If the top-left corner of the rectangle was defined by the coordinates  $I_0$  and  $J_0$ , and the bottom-right corner by  $I_1$  and  $J_1$ , then the integral value of the region is defined by the following formula.

$$\iint_{\text{Region}} \text{Inp}_{i,j} = \sum_{j=J_0}^{J_1} \sum_{i=I_0}^{I_1} \text{Inp}_{i,j} = \text{SAT}_{I_1,J_1} - \text{SAT}_{I_1,J_0-1} - \text{SAT}_{I_0-1,J_1} + \text{SAT}_{I_0-1,J_0-1}$$

Similarly, the RSAT map can be used to quickly determine the integral of rotated regions as shown in the following figure.

**Figure 30-22:** Use of RSAT Map

## Data Types

IIM blocks feature a 33-bit adder to operate on 32-bit data. The 33rd bit is used for overflow management. If the adder overflows, it does not saturate but continues normal operation. Software may post-analyze the integral map to track overflows. The occurrence of an overflow depends on the input data format. For 10-bit input data, the integral counter should never overflow over the region or even the full frame.

The occurrence of overflows can be controlled by reducing the resolution of the incoming data. The `PVP_IIMx_CTL.SHIFT` control field instructs the IIMx block to arithmetically right shift input data. It can shift from 0 to 31 bit positions to the right.

The IIM blocks can operate on signed and unsigned data. There is no control bit to distinguish between signed and unsigned mode. Rather, there are two different sets of status reports. The event of unsigned overflow is reported by the `PVP_STAT.IIMxUOVF` bits. When flagged, the `PVP_IIMx_UOVF_STAT` register latches the coordinates of the data that caused the overflow. Similarly, the `PVP_STAT.IIMxSOVF` bits report signed overflows and the `PVP_IIMx_SOVF_STAT` register latches the coordinates.

The adder can be configured to operate in dual 16-bit mode or in quad 8-bit mode, alternatively. This is controlled by the `PVP_IIMx_CTL.WIDTH` field. In these modes each IIMx block can perform dual or quad integral operations concurrently, for the price of having increased likelihood of overflows. The overflow reporting mechanism works the same as in the 32-bit mode where it monitors overflows in the topmost word or byte. In dual 16-bit mode or in quad 8-bit mode the input shifter performs an unsigned right shift operation rather than an arithmetical operation as in 32-bit mode.

The quad 8-bit mode is most useful when the integral block connects to port 1 of the PEC. In this case the IIMx generates the integral over the 1st or 2nd derivative gradients. Dual 16-bit mode might connect to port 2 of the PMA. In this case the lower part of the adder builds the integral over the magnitude while the upper half integrates the angle. Alternatively, port 2 of the PMA might be routed through one of the THCx blocks for quantization of the magnitude.

## Controlling Bandwidth

In many cases the IIMx blocks receive input data with a relatively low bit count. The output however, is always 32 bits wide. If not used with care the IIMx blocks can be significant consumers of system memory bandwidth. If the 32-bit resolution is not required at the output, the connected output formatter may only take the upper or the lower 16 bits of the result. To take the lower bits, set `PVP_OPFx_CTL.ISIZE = 1` and `PVP_OPFx_CTL.IUP16 = 0`. To take the upper bits, set `PVP_OPFx_CTL.ISIZE = 1` and `PVP_OPFx_CTL.IUP16 = 1`. Together with the `PVP_IIMx_CTL.SHIFT` setting the weight of the integral can be controlled.

Another way of reducing bandwidth used by the integral blocks is by scaling the IIMx output. The `PVP_IIMx_SCALE` register can individually enable sub-sampling of rows or columns on the output in power-of-2 steps as follows.

- If `VSCL = 0`, no vertical scaling is performed and all rows are output.
- If `VSCL = 1`, the IIMx outputs only every other row and if `VSCL = 3`, it outputs only every 4th row.
- If `HSCL = 7`, the IIMx outputs only every 8th column.

## Connectivity

Both integral blocks can receive their inputs from a large variety of modules. They can build the integral on raw data inputs when receiving data from the input formatters. Input data can optionally be filtered by convolutions. Variances can be calculated by squaring the inputs by the ACU before building the integral. If connected to the PMA blocks, integral of edge magnitude and gradients can be built. Histogram of gradients can be done by sensing port 1 of the PEC block. If connected to the THC<sub>x</sub> blocks, the integral of a binary edge map can be generated, or data is clipped up front by the THC<sub>x</sub> blocks.

**Table 30-27:** IIMx Block Connectivity

| Input 0                                                     | Block                                                                             | Port                                                               | Input 1 | Block | Port | Output                                                      |

**Figure 30-23:** IIM0 Connectivity

## Up Down Scaler (UDS)

The UDS is an image resizing block. The UDS is the only block which cannot operate in the camera pipe. The input to UDS comes from IPF1 while the output drives OPF3 as shown in the figure below.

**Figure 30-24:** UDS Block Connections

The UDS block expects 16-bit or 32-bit unsigned input data and drives 32-bit unsigned output data. When an anti-aliasing or an averaging filter is enabled, the input must be 16 bits and correspondingly the output is 16 bits presented in the lower 16 bits of the 32-bit output.

The figure below shows the data flow within the UDS block. The block performs horizontal scaling followed by vertical scaling in two independent steps. The interpolation uses bilinear arithmetic.

**Figure 30-25:** UDS Overview

The key features of the block are as follows.

- Supports input frame sizes from 10x10 to 1280x960. The frame size is programmed in the PVP\_IPF1\_HCNT and PVP\_IPF1\_VCNT registers of IPF1.
- Supports independent scaling in both directions. The output frame size is selectable in steps of 16. The values supported are:  $16 \times n \times 16 \times m$  where  $n, m = 1, 2, \dots, 8$ . The output size is programmed in the PVP\_UDS\_OHCNT and PVP\_UDS\_OVCNT registers.
- Supports an optional anti-aliasing filter in the form of an averaging filter in both directions. The filter has an option to calculate the number of taps automatically or takes a user programmable value. If the PVP\_UDS\_CTL.AAVG bit = 1 then the number of taps are selected automatically based on the input and output frame size. If the bit = 0 then the number of taps must be programmed in the PVP\_UDS\_HAVG and PVP\_UDS\_VAVG registers. The UDS supports a maximum of 128 taps for horizontal direction and 64 taps for vertical direction.
- Supports an averaging filter only for 16-bit input data. The averaging filter must be disabled for 32-bit input data by setting the PVP\_UDS\_CTL.AAVG bit = 0, the PVP\_UDS\_HAVG.VALUE = 1, and the PVP\_UDS\_VAVG.VALUE bit = 1. The filter is bypassed when the number of taps is 1.

The number of taps for each direction in automatic mode is calculated as:

$$N\_TAPS = \left\lfloor \frac{Source\_Dimension}{Target\_Dimension} \right\rfloor$$

where  $\lfloor x \rfloor$  denotes integer part of x. In user programmable mode the number of taps is limited by the following equation.

$$N\_TAPS \leq \left( 2 * \frac{Source\_Dimension}{Target\_Dimension} \right) - 1$$

If an output pixel requires input pixels beyond the edges then the nearest pixel on the edge is used for computation. In effect edge pixels are duplicated from the nearest valid pixel.

## Architectural Concepts

The PVP unifies two architectural concepts, the camera pipes and the memory pipe. The camera pipes serve the preprocessing requirements. Data is preprocessed on its way from the PPI input to the system memory and can be broadcast from one single video source to up to three functional branches called camera pipes. The memory pipe functions as a Co-processor. It loads input data from system memory via DMA and stores results back to system memory the same way.

Camera pipes and memory pipes can operate concurrently. They have completely separate control mechanisms and data paths and are completely independent in timing. Both pipes share, however, twelve signal processing blocks. The user has full flexibility in assigning each of the processing blocks to any pipe. The one exception is the up/down-scaler block that can only operate in memory pipe mode. Certainly, each block can be assigned only once at a given time. However, there is support for dynamic re configuration of the assignments. The blocks are:

- Two input formatters (IPFx, x=0, 1) supporting selection of input streams, gating pipeline processing clock, extraction of color or luminance components, windowing region of interest, separation of odd and even bit stream vectors (pixels) and frame counting. IPF0 receives input data from the video subsystem and feeds data to the camera pipes. IPF1 receives data from memory via DMA and services the Memory Pipe.
- Four convolution blocks (CNVx, x=0, 1, 2, 3) supporting 2-dimensional 5x5 convolution of data streams and constant coefficients, vector downscaling, data shifting, and data normalization.
- One polar magnitude and angle block (PMA) supporting data conversion from Cartesian form (X, Y) to a polar form (magnitude, angle).
- One pixel edge classifier (PEC) supporting edge detection in 2-dimensional data arrays using 2-dimensional 1<sup>st</sup> or 2<sup>nd</sup> derivation.
- One arithmetic unit (ACU) supporting 32-bit arithmetic operations (product, sum, accumulation, shift, maximum, minimum).

- Two threshold-histogram-compression cells (THCx, x=0, 1) supporting data formatting (clipping, saturation), data quantization (binning), multi-level hysteresis and data compression.
- Two integral image blocks (IIMx, x=0, 1) supporting integrals of rows and diagonals.
- One Up-down scaler (UDS) supporting interpolation and extrapolation of 2-dimensional data arrays.
- Four output formatters (OPFx, x=0, 1, 2, 3) supporting selection of output streams, data packing, and buffering (FIFO) output data streams. They collect the processing results and forward them to dedicated DMA channels.

## Operating Modes

Following sections provide operating mode examples, describing how the PVP can be used to implement typical vision-system operations.

### Thresholds and Histograms

The THCx block can be used for a variety of purposes. One example where the input data range is reduced to 4-bits and computation of 16-level histogram is shown in the figure below.

**Figure 30-26:** Computation of 16-level Histogram

In camera pipe mode, CNV0 receives data from port 0 of input formatter IPF0. The CNV0 block can do low pass filtering to eliminate noise and can optionally down scale the input for the THC0 block.

The THC0 block operates in the quantization mode by setting the `PVP_THC0_CTL.MODE` bit = 1. The threshold values are set in the `PVP_THC0_Thy` (y = 0–15) registers. The block is programmed to output a 4-bit index without any compression when the `PVP_THC0_CTL.OFRMT` bit = 2.

The histogram function is enabled by setting the `PVP_THC0_CTL.HISTEN` bit = 1. The number of frames used to perform the histogram operation is set in the `PVP_THC0_CTL.HFCNT.VALUE` bit field.

The OPF0 is set to pack the 4-bit output from THC0 to a 32-bit word when the `PVP_OPF0_CTL.ISIZE` bit = 3 and the `PVP_OPF0_CTL.OSIZE` bit = 0. The histogram values are read using the status DMA channel.

The values can also be read by directly by accessing the PVP\_THCO\_HCNT<sub>y</sub>\_STAT (y = 0–15) registers. The PVP\_THCO\_HFCNT\_STAT register indicates the current frame counter number to which the histogram values have been accumulated.

## Sobel with 3x3 or 5x5 Matrix Operation

The following figure shows a simple Sobel use case example. The Sobel algorithm is a standard algorithm used for edge detection applications. One convolution block is used to determine the horizontal component of 1st-derivative edge gradients, and another convolution block determines the vertical component. In camera pipe mode, both convolution blocks receive data from port 0 of input formatter IPF0.

**Figure 30-27:** Sobel Data Flow

Traditional Sobel operators require simple 3x3 convolution matrices. The 5x5 coefficient matrices of the convolution blocks might be filled with 16-bit values as shown below.

$$Coeff_{CNV0} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & -1 & 0 \\ 0 & 2 & 0 & -2 & 0 \\ 0 & 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} \quad Coeff_{CNV1} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & -2 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

**Figure 30-28:** Traditional 3x3 Sobel Coefficients

Larger Sobel kernels can be realized using 5x5 operators. One option is the following set of coefficients.

$$Coeff_{CNV0} = \begin{pmatrix} 1 & 2 & 0 & -2 & -1 \\ 4 & 8 & 0 & -8 & -4 \\ 6 & 12 & 0 & -12 & -6 \\ 4 & 8 & 0 & -8 & -4 \\ 1 & 2 & 0 & -2 & -1 \end{pmatrix} \quad Coeff_{CNV1} = \begin{pmatrix} -1 & -4 & -6 & -4 & -1 \\ -2 & -8 & -12 & -8 & -2 \\ 0 & 0 & 0 & 0 & 0 \\ 2 & 8 & -12 & 8 & 2 \\ 1 & 4 & 6 & 4 & 1 \end{pmatrix}$$

**Figure 30-29:** Example of 5x5 Coefficients

The inputs of the subsequent PMA blocks should be 16-bit signed data. Therefore, care is required in dealing with data formats and bit growth. If IPF0 receives 14-bit unsigned data that is zero-extended to 16-bits, the 3x3 Sobel operation has a bit growth of 2 in each convolution block's accumulator. Additionally, the result is signed, making it a 17-bit signed value. Therefore, both convolution outputs need to be normalized by shifting two positions to the right (`PVP_CNVx_CTL.SHIFT = 2`). Alternatively, the accumulation results can be saturated to 16-bit signed values if no shift is performed and the `PVP_CNVx_CTL.SAT32` bit was kept clear.

If the input formatter receives 16-bit signed values and the above 5x5 coefficient matrix is used, then the accumulator holds 22-bit signed values and a `PVP_CNVx_CTL.SHIFT = 6` setting is required.

$$Magnitude = \sqrt{|x|^2 + |y|^2} \quad \varphi = \arctan\left(\frac{y}{x}\right)$$

**Figure 30-30:** PMA Operation

The PMA block takes the 16-bit signed Cartesian values from the two convolution operations. The PMA block converts the inputs to Polar values resulting in magnitude and the angle of the resulting gradients. The magnitude is a 16-bit unsigned format, and the angle is a 5-bit unsigned value.

## Sobel Output Formats

The PMA block has three output ports. Port 0 outputs the 16-bit unsigned magnitude, port 1 outputs the 5-bit angle and port 2 outputs the combination of the two: the lower 16 bits contain the magnitude and bits 20:16 contain the angle. All three ports zero fill the upper bits if connected to 32-bit data sinks.

If a system is only interested in the 16-bit magnitude values, then one of the output formatters is programmed to input data from PMA port 0 or from port 2. Likewise, the output formatter uses 16-to-32-bit packing and sets `PVP_OPFx_CTL.ISIZE = 1`, `PVP_OPFx_CTL.IUP16 = 0` and `PVP_OPFx_CTL.OSIZE = 0`.

If a system is only interested in the 5-bit magnitude values, then one of the output formatters is programmed to input data from PMA port 1. Likewise, the output formatter uses 8-to-32-bit packing and

sets `PVP_OPFx_CTL.ISIZE = 2`, `PVP_OPFx_CTL.IUP16 = 0` and `PVP_OPFx_CTL.OSIZE = 0`. Alternatively, the OPF can take data from port 2 and set `PVP_OPFx_CTL.IUP16 = 1`.

If, however, the system wants to use both magnitude and angle values, two output formatters can be used. However, for best system resource use it is recommended to only use one output formatter that inputs data from PMA port 2 in 32-bit mode where (`PVP_OPFx_CTL.ISIZE = 0`).

Often, an application does not require 16 bits of magnitude resolution. Rather, only one bit (binary edge map) or only a few bits are wanted. In this case, the threshold blocks are used as shown in the following figure.

**Figure 30-31:** Thresholded Edge Map Data Flow

A binary edge map can be generated by the THC<sub>x</sub> using quantization mode. The `PVP_THCx_TH0` register is set to zero and the `PVP_THCx_TH1` register defines the threshold. If the output format is set to the 4-bit floor value (`PVP_THCx_CTL.OFRMT = 1`), a 4-bit magnitude value is sent. The connected output formatter may perform 4-to-32-bit packing by the setting the `PVP_OPFx_CTL.ISIZE` bit = 3. All 16 thresholds can be configured to apply a non-linear quantization of the magnitude value. Alternatively, hysteresis mode can be used. Clipping mode, when paired with `PVP_THCx_CTL.OFRMT = 0`, can be used to output user-programmable 32-bit values when the magnitude is above the threshold.

On the input side, the THC<sub>x</sub> blocks provide multiple options: if they sense Port 0 of the PMA block, they receive 16-bit values that are zero-extended to 32 bits. If they sense Port 2 instead, the 5-bits of might be unwanted. Then, the `PVP_THCx_CTL.ZEXT = 1` setting helps masking the upper 16 bits. This feature becomes most interesting when partnering with the `PVP_THCx_CTL.OFRMT = 4` option. This way, the THC generates an output format that groups the 4-bit floor value of the magnitude with the four significant bits of the PMA angle. The Output Formatter is best set to `PVP_OPFx_CTL.ISIZE = 2` mode.

## Canny with PEC in 1st-Derivative Mode

The following figure shows a Canny use case example. The Canny algorithm is a standard algorithm for edge detection applications. The input pixels are first low pass filtered to remove noise by CNV0. One convolution block is used to determine the horizontal component of 1st-derivative edge gradients, and another convolution blocks determines the vertical component as in the Sobel case. In camera pipe mode, the CNV0 block receives data from port 0 of IPF0.

**Figure 30-32:** Canny Data Flow

The 5x5 Gaussian kernel (Sigma = 1) for low pass filtering is shown in the figure below.

$$Gaussian\ Kernel = \frac{1}{330} \begin{bmatrix} 1 & 4 & 7 & 4 & 1 \\ 4 & 20 & 33 & 20 & 4 \\ 7 & 33 & 54 & 33 & 7 \\ 4 & 20 & 33 & 20 & 4 \\ 1 & 4 & 7 & 4 & 1 \end{bmatrix} \quad Coeff_{CNV0} = \begin{bmatrix} 0x0063 & 0x018d & 0x02b7 & 0x018d & 0x0063 \\ 0x018d & 0x07c2 & 0x0ccd & 0x07c2 & 0x018d \\ 0x02b7 & 0x0ccd & 0x14f2 & 0x0ccd & 0x02b7 \\ 0x018d & 0x07c2 & 0x0ccd & 0x07c2 & 0x018d \\ 0x0063 & 0x018d & 0x02b7 & 0x018d & 0x0063 \end{bmatrix}$$

**Figure 30-33:** Gauss Filter

The fractional values are converted to 1.15 format and programmed into the coefficient registers of CNV0. The output is shifted right by 15 bits to remove the fractional part by setting `PVP_CNV0_CTL.SHIFT` to 15.

The low pass filtered output feeds the two convolution blocks which generate the gradients as described in the Sobel use case example. The PMA block takes the 16-bit signed Cartesian values from the two convolution operations. The PMA block converts the inputs to polar values that result in magnitude and the angle of the resulting gradients. The magnitude is in a 16-bit unsigned format, and the angle is a 5-bit unsigned value.

The PEC block interfaces to PMA port 2 which has the magnitude and angle packed into a 32-bit word. The PEC performs the non-maximum suppression to produce thin edges and hysteresis threshold to allow software to reduce streaking. Since the PEC works on the output from 1st derivative filters, it should be configured for mode 1 by setting `PVP_PEC_CTL.MODE` to 0. The threshold values for magnitude comparison is set in `PVP_PEC_D1TH0` register (lower threshold) and the `PVP_PEC_D1TH1` register (higher threshold). Hysteresis thresholding can be selectively disabled by setting `PVP_PEC_CTL.IGNTH1` to 1.

The OPF can be set to sense PEC port 0 which carries the 8-bit encoded output. The post-processing software can use this output for edge tracing and further processing. The OPF should be configured to `PVP_OPF0_CTL.ISIZE = 2` and `PVP_OPF0_CTL.OSIZE = 0`.

## LoG with PEC in 2nd-Derivative Mode

Laplacian on Gaussian (LoG) is an edge detection algorithm based on 2nd derivative filtering of an input image. The LoG method produces thin edges but is sensitive to noise. Therefore the input image is filtered

using a Gaussian kernel before convolving with the LoG kernel. The PEC block produces the angle information which is missing in the traditional LoG algorithm. The post-processing software can use the class/angle information from the PEC to build contours for further analysis.

**Figure 30-34:** LoG Data Flow

The CNV0 use the same Gaussian kernel described in the Canny use case example. The LoG kernel is shown in the figure below.

$$LoG\ Kernel = \frac{1}{16} \begin{bmatrix} 0 & 0 & -1 & 0 & 0 \\ 0 & -1 & -2 & -1 & 0 \\ -1 & -2 & 16 & -2 & -1 \\ 0 & -1 & -2 & -1 & 0 \\ 0 & 0 & -1 & 0 & 0 \end{bmatrix} \quad Coeff_{CNV1} = \begin{bmatrix} 0 & 0 & 0xf800 & 0 & 0 \\ 0 & 0xf800 & 0xf000 & 0xf800 & 0 \\ 0xf800 & 0xf000 & 0x7fff & 0xf000 & 0xf800 \\ 0 & 0xf800 & 0xf000 & 0xf800 & 0 \\ 0 & 0 & 0xf800 & 0 & 0 \end{bmatrix}$$

**Figure 30-35:** LoG Coefficients

The coefficients are programmed in 1.15 format in the CNV1 registers. The fractional part is eliminated in the output of CNV1 by setting `PVP_CNV1_CTL.SHIFT = 15`.

The PEC block interfaces to the CNV1 output. The PEC computes angle information and sub-pixel location of the edges. Since the PEC works on outputs from 2nd derivative filters, it should be configured to mode 2 by setting `PVP_PEC_CTL.MODE = 1`. The threshold values for zero crossing detection is set in the `PVP_PEC_D2TH0` (lower threshold) and `PVP_PEC_D2TH1` (higher threshold) registers. The strong/weak edge distinction can be selectively disabled by setting `PVP_PEC_CTL.IGNTH1 = 1`. The PEC can output either the zero-crossing codes (`PVP_PEC_CTL.ZCRSS = 1`) or the angle information (`PVP_PEC_CTL.ZCRSS = 0`) from the classifier. In both cases the output on port 0 is in 8-bit packed format and contains the sub-pixel location in the upper 4-bits and either zero-cross code or angle index.

The OPF can be set to sense port 0 of the PEC which carries the 8-bit encoded output. The post-processing software can use this output for building contours and further processing. The OPF should be configured to `PVP_OPF0_CTL.ISIZE = 2` and `PVP_OPF0_CTL.OSIZE = 0`.

The following figure demonstrates how both 1st derivative and 2nd derivative edge detection methods can be realized concurrently in the PVP.

**Figure 30-36:** Concurrency of Sobel and LoG Methods

The CNV2 performs the initial low-pass filtering to remove noise in the input data. The output is broadcast to the three CNV blocks. The lower signal pipe using CNV3-PEC realizes the 2nd derivative method of edge detection using the LoG method. The upper signal pipe realized the 1st derivative method of edge detection using the Sobel method. The outputs are captured using 2 OPFs concurrently.

## DoG with PEC in 2nd-Derivative Mode

Difference of Gaussian (DoG) is an edge detection algorithm which approximates the 2nd derivative filtering of an input image. The input image is filtered by two Gaussian kernels with different sigma. The resulting output is subtracted to produce an output similar to the filtering using LoG kernel. This output is fed to PEC which works in the same manner as in LoG method. The post-processing software can use the class/angle information from PEC to build contours for further analysis. The figure below shows the data flow for the DoG method.

**Figure 30-37:** Difference of Gaussian Data Flow

The input data is first convolved with Gaussian kernel in CNV0. The output is convolved a second time with a Gaussian kernel in CNV1. The resulting output is the result from convolving the original image with a 9x9 Gaussian kernel of sum of sigmas of CNV0 and CNV1. The output from CNV0 can be subtracted

from the output of CNV1 using the ACU. But the two outputs have to be matched for the delay to subtract the pixels at the right instant/location. This is achieved by inserting CNV2 which doesn't modify the data but just matches the delay introduced by CNV1. The kernel for bypassing the input to the output is shown below.

$$Coeff_{CNV2} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

**Figure 30-38:** Bypass Coefficients for CNV2

Note that PEC and OPF settings are the same as in the LoG example.

## Integral of Input Pixels

The IIMx block can be used to compute integral of input pixels as shown in the figure below.

**Figure 30-39:** Integral Image of Input Pixels Data Flow

In camera pipe mode, IIM0 receives data from port 0 of IPF0. The IIM0 can be used to compute Sum-Area-Table (SAT) features by setting `PVP_IIM0_CTL.MODE = 0`. If Rotated-Sum-Area-Table (RSAT) features are required then configure `PVP_IIM0_CTL.MODE = 1`.

Since the integral is computed on single pixels coming in from IPF0, the `PVP_IIM0_CTL.WIDTH = 0` (32-bit input). Note that IPF0 zero extends the incoming pixel values to 32-bits before placing on them on port 0.

In order to reduce the occurrences of overflow/underflow while performing the integral, the IIM supports reducing the input range by shifting the LSBs out of incoming data. The `PVP_IIM0_CTL.SHIFT` bits can be set to a non-zero value to reduce the pixel data range. The IIM can optionally also scale down the output data in horizontal and vertical directions independently. The `PVP_IIM0_SCALE.HSCL` and `PVP_IIM0_SCALE.VSCL` fields can be used for setting the scale factors.

For best operation, set the OPF to receive and transmit 32-bit data using the following bit configuration (PVP\_OPF<sub>x</sub>\_CTL.ISIZE = 0, PVP\_OPF<sub>x</sub>\_CTL.OSIZE = 0).

## Integral of Binary Edge Map

The IIMx block can interface to the THCx to compute integral of edge map as shown in the figure below.

**Figure 30-40:** Integral Image of Binary Edge Map Data Flow

The edge map is generated as described in the Sobel use case example. The 4-bit index output from the THC0 block forms the input to the IIM0 block. By properly choosing THC0 registers (TH0 = 0, TH1 = threshold value and TH2-TH15 = maximum of 16-bit value,  $2^{16}-1$ ) the output from the THC0 block is only 0 and 1, a true binary edge map. The IIM0 block is configured in different modes as explained in the previous example.

## Integral of Variance

The IIMx block can interface to the ACU block to compute integral of squared input values. The input data from IPF0 can be fed to both inputs of the ACU as shown in the figure below.

**Figure 30-41:** Integral of Squared Input Values Data Flow

The ACU is set to multiply the input operands (PVP\_ACU\_CTL.SFTINP = 2, PVP\_ACU\_CTL.PRDIINP = 0, PVP\_ACU\_CTL.PRODDP = 0, PVP\_ACU\_SHIFT = 0). The ACU also supports user programmable clipping with values from the PVP\_ACU\_MIN and PVP\_ACU\_MAX registers. The IIM1 block is configured in different modes as explained in the previous example.

## Histogram of Gradients (HoG)

The IIMx block can be used to compute Histogram of Gradients (HoG) features by interfacing to port 1 of the PEC block as shown in the figure below.

**Figure 30-42:** Histogram of Gradients Data Flow

The PEC block port 1 carries angle information in either 8-bit or 16-bit fields. This format is supported in both modes (1st and 2nd derivative) of the PEC. Port 1 is not valid only when `PVP_PEC_CTL.ZCRSS = 1` in 2nd derivative mode because the angle is not functional.

When the PEC is programmed to output 8-bits per angle bin, (`PVP_PEC_CTL.OSIZE = 0`), there are four angle bins in a 32-bit word output. The IIM0 computes the integral of the individual bins and IIM0 must be set in quad 8-bit mode, (`PVP_IIM0_CTL.WIDTH = 3`).

When the PEC is programmed to output 16-bits per angle bin, (`PVP_PEC_CTL.OSIZE = 1`), there are two angle bins in a 32-bit word output. The IIM0 computes the integral of the individual bins and IIM0 must be set in dual 16-bit mode, (`PVP_IIM0_CTL.WIDTH = 1`).

For optimal operation, set the OPF to receive and transmit 32-bit data (`PVP_OPF0_CTL.ISIZE = 0`, `PVP_OPF0_CTL.OSIZE = 0`).

## Event Control

This section describes PVP event control issues, including interrupt signals, status/error signals, and finish commands.

### Interrupt Signals

Although the PVP features two interrupt outputs, much of the software interaction occurs through the interrupts of the associated DMAs. For example, the PVP interrupt may signal that a frame has been completely received and processed, but only the completion interrupt of the data output DMA can tell whether all results are stored in system memory.

The PVP features a single, 32-bit wide event status register, `PVP_STAT`, as shown in figure below. It contains read-only status bits for camera pipe control, memory pipe control and individual processing blocks. All flags in this register are generated and cleared by hardware.

The PVP\_ILAT register contains the latched counterparts of the status bits in the PVP\_STAT register. If a status bit toggles from 0 to 1 the respective latch bit is set automatically. The latches in the PVP\_ILAT register are cleared by software using the W1C method.

**Figure 30-43:** Interrupt Flow

The two PVP\_IMSKx registers can unmask the interrupt behavior of the latches. If bit 13 in the status register (PVP\_STAT.CPRDY, camera pipe ready) is set by hardware, then latch 13 PVP\_ILAT.CPRDY is also set. By default interrupts are not yet requested. If software sets bit 13 of the PVP\_IMSK0 register, then the CPRDY bit causes an interrupt on the INTR\_PVP\_STAT0 output. If however software sets bit 13 of PVP\_IMSK1, the CPRDY event triggers an interrupt on the INTR\_PVP\_STAT1 output.

On the ADSP-BF609 processor the STAT0 output is connected to system event channel 115 and the STAT1 output is connected to channel 121.

The two PVP\_IREQx registers can be read by software to determine which of the interrupts enabled on a respective channel is pending. Interrupt request bits are a logical AND of mask and latch bits. The interrupt outputs are the logical OR of all interrupt requests in the given PVP\_IREQx register.

Software can acknowledge interrupts by a W1C operation to either the PVP\_IREQx or the PVP\_ILATx registers. Either operation clears the latches in the respective PVP\_ILATx register.

## Status and Error Signals

All PVP status and error events are reported by the `PVP_STAT` register. It is noted that further interrupts and error signals out of PPI, PIXC and DMA channels are highly relevant to PVP operation.

The `PVP_STAT` register contains the following status and error bits for pipe control. There is always one status bit for the camera pipe and one for the memory pipe:

- **Daisy Chain Completion.** The `CPDC` and `MPDC` bits signal whether a configuration update is currently daisy chaining through the pipe. The bits are set along with the `PVP_IPFx_CFG.START` bit and are cleared if all blocks in the pipe have been updated.
- **Write Error.** The `CPWRERR` and `MPWRERR` bits are set when an MMR write is attempted during ongoing daisy chaining of configuration and are cleared at the end of the daisy chain operation.
- **Completion of Drain operation.** The `CPDRN` and `MPDRN` bits get set when the pipe has finished draining in response to `PVP_IPFx_PIECTL.DRAIN` bit. The bits are cleared when `PVP_IPFx_CFG.START` is set next time.
- **Pipe Ready.** The `CPRDY` and `MPRDY` bits indicate that the respective pipe is ready for a new configuration. They are set along with the drain completion bits and cleared by daisy chain completion.

The `PVP_STAT` register contains the following status bit for the data flow.

- **Data Events.** The `CPOPFDAT` and `MPOPFDAT` bits are set when all enabled output formatters have processed the first data word. The bits are cleared with the next data row.

The `PVP_STAT` register contains the following error bits for signaling data transfer errors in camera pipe. Since the memory pipe is designed to not overflow it does not need the following error flags.

- **Output FIFO Overflow.** The `OPF0OVF`, `OPF1OVF` and `OPF2OVF` bits are set when the FIFO overflows, which is fed by OPF outputs and drained by data output DMA. The bits are cleared when the first data value of the next row is processed by the OPF.
- **Status FIFO Overflow.** The `CPSTOVF` flag is similar to `OPFxOVF` bits. It is set when the status output FIFO overflows.
- **Input Overflow.** The `CPIPF0VF` flag is set when data overflows at IPF0. This flag can only be cleared by a camera pipe disable (`PVP_CTL.CPEN = 0`).

The `PVP_STAT` register contains the following status and error bits to report the status of individual processing blocks.

- **Histogram Ready.** The `THCORDY` and `THC1RDY` bits indicate that the THC histogram counters have been updated. Set at the end of a frame when `PVP_IPFx_FCNT = zero` or has counted down to zero and `PVP_IPFx_PIECTL.STATEN = 1`.
- **Integral Unsigned Overflow.** The `IIM0UOVF` and `IIM1UOVF` bits are set when bit 31 of the integral counter in the IIM overflowed during an on-going frame.

- **Integral Signed Overflow.** The IIM0SOVF and IIM1SOVF bits are set when bit 30 of the integral counter in the IIM overflowed during an on-going frame
- **Divide by Zero.** The ACUDIVERR bit is set by the ACU when a divide-by-zero operation was attempted during the on-going frame.
- **ACU Output Saturation.** The ACUOUTSAT bit is set when, during the on-going frame, data was saturated due to the PVP\_ACU\_MIN/PVP\_ACU\_MAX mechanism.
- **ACU Multiplication Saturation.** The ACUPRODSAT bit is set when, during the on-going frame, a multiplication product was saturated.
- **ACU Addition Saturation.** The ACUSUMSAT bit is set when, during the on-going frame, the sum of an addition or subtraction was saturated.

## Finish Commands

Output formatters are the blocks that drive data output DMAs. They use a special DMA feature where they can on demand send a finish command to the DMA channel to signal that the work unit has completed.

The three camera pipe output formatters, OPF0, OPF1 and OPF2 send a finish command when the FIFO overflows. When this occurs, the overflow is reported to the PVP\_STAT register, the FIFO is cleared, and a finish command is sent to the DMA channel at the end of the corrupted frame. The PVP and DMA automatically re synchronize with the next frame boundary. Due to the large depth of the data output FIFO, multiple frames may stick in the FIFO by the time the error occurs. In case of very small frames software may not know whether the automatic recovery dropped one or multiple frames.

The Finish command is also used for signaling. The PVP\_OPF<sub>x</sub>\_CTL.FINISH bit configures this operation. When set, the respective output formatter always issues a Finish command at the end of each frame. This feature is valuable when the exact amount of transfers per frame is not known.

A good example is with run-length compression mode, where the number of output reports generated depends on the incoming data. The DMA work unit is pre configured for a certain number of transfers and only completes if all transfers have taken place. Typically, the run-length compression output DMA is set to the maximum value of reports a frame can generate. This value depends on the PVP\_THC<sub>x</sub>\_RMAXREP register setting. If PVP\_OPF<sub>x</sub>\_CTL.FINISH = 1 the output DMA can terminate before all DMA transfers have occurred. The DMA can immediately progress to the next frame's operation. When using this feature, software needs to be aware that not all memory cells reserved for the operation might be filled with new value.

## Programming Model

This section describes PVP programming techniques, including configuration for pipes, blocks, daisy chains, job lists, and reports.

## Configuring Pipe Structure

Most PVP processing blocks have a single fixed output while others have multiple outputs. The PVP also has one or two inputs that contain multiplexers. This allows system designers to choose what block output the input should be connected to.

The pipeline structure is composed by programming multiplexers from the outputs back to the inputs. By definition, this starts with one of the OPF blocks. For example, if the input of OPF0 is assigned to one of the three output ports of an empty camera pipe on IPF0, a camera pipe without any mathematical mean has been created. If, however, the input of OPF0 is assigned to the output of THC1, and the input of THC1 is assigned to an output of IPF0, a camera pipe with a single mathematical function has been created.

To continue the example, one output of the IPF0 can perform 3-way data broadcasting with the following configuration.

- OPF1 input is connected to the IIM0 output
- The IIM0 input is connected to the ACU output
- The ACU has two inputs and both inputs are connected to the same output of IPF0 and THC1

Similarly, to configure OPF2 to probe the PMA's output use the following configuration.

- Connect the two PMA inputs to CNV1 and CNV2
- Connect these to CNV0's output
- CNV0's input finally receives data from a different port of IPF0

The following diagram illustrates this example. Additionally, it shows the UDS block configured in memory pipe between OPF3 and IPF1.

**Figure 30-44:** Pipe Structure Example Configuration

The next figure shows the data flows in the same example configuration. Note the broadcast at the IPF0 and CNV0 outputs. Note also how threads are united by the ACU and PMA blocks.

**Figure 30-45:** Data Flow in Example Configuration

Although the example above has significant processing power, it does not use the THC0, IIM1, CNV3 and PEC processing blocks.

To program the input multiplexers, each processing element features a pipe configuration register. The `PVP_xxx_CFG.IBLOCK0` bit field specifies the identifier of the desired source block. The `PVP_xxx_CFG.IPORT0` field is used if the selected source block has multiple outputs. Since the PMA and ACU have two inputs, their configuration register consistently features the `IBLOCK1` and `IPORT1` fields.

**Figure 30-46:** Input Port Selection

**Table 30-28:** Block IDs

| Block | Block ID | Block | Block ID | Block | Block ID | Block | Block ID |
|-------|----------|-------|----------|-------|----------|-------|----------|
| OPF0  | 0x01     | OPF1  | 0x02     | OPF2  | 0x03     | OPF3  | 0x04     |
| IPF0  | 0x0C     | IPF1  | 0x0E     | THC0  | 0x20     | THC1  | 0x28     |
| CNV0  | 0x10     | CNV1  | 0x14     | CNV2  | 0x18     | CNV3  | 0x1C     |
| ACU   | 0x08     | PMA   | 0x30     | PEC   | 0x05     | UDS   | 0x0A     |
| IIM0  | 0x06     | IIM1  | 0x07     |       |          |       |          |

It is mandatory that all blocks that are used have their `PVP_XXX_CFG.MPIPE` bit properly configured. All blocks that contribute to the OPF3 output, (all blocks operating in the memory pipe), must have the `MPIPE` bit set. For all non contributors, the `MPIPE` bit must be cleared.

**NOTE:** It is user's responsibility to ensure that the `MPIPE` settings match with the assignments of OPF0-2 versus OPF-3. Broadcasts and unions from the camera pipe to the memory pipe and vice versa are absolutely forbidden.

A valid pipe always starts at the input formatter and ends at the output formatter with one exception. Pipes can end at the THC blocks if the data output of the THC blocks is not of interest. Then, the THC blocks

can still operate in histogram mode, where the histogram is outputted to the status DMA. A limitation applies in that such a histogram-only THC setup cannot partner with UDS block in memory pipe mode.

Figure 30-47: Block Connectivity Overview

## Register Based Camera Pipe Configuration

To configure the camera pipe in the static way, use the register-based programming method. In this case all pipe control and processing blocks can be programmed by writing configuration and coefficients into memory-mapped registers (MMRs). Typically, the following procedure is used.

1. Disable all involved PVP blocks, all involved VSS elements and all involved DMA channels to ensure that all data FIFOs are empty
2. Configure video interconnect routing
3. Configure pin muxing for PPI input operation
4. Set the `PVP_CTL.PVPEN` and `PVP_CTL.CPEN` bits to enable camera pipe mode
5. Configure and enable all output DMAs using either the register-based or the descriptor-based method.
6. Configure all camera pipe processing blocks starting from the output formatters to IPF0. Ensure that the structure of the camera pipes are configured using the `PVP_XXX_CFG` registers and ensure that the appropriate `MPIPE` bits are cleared and the appropriate `START` bits are set.

7. Enable the IPF0 block. If continued camera pipe operation is desired, set `PVP_IPF0_FCNT = 0`. Finally, setting the `PVP_IPF0_CFG.START` bit enables the entire camera pipe.
8. Configure PPI DMAs
9. Enable the PPI (and optionally the PIXC)

Once all blocks are enabled the PVP operation starts with the next vertical frame sync (VSYNC). There is some flexibility in the order of above procedure. For example, the PVP camera pipe can be reconfigured while the PPI is kept enabled. Then, the camera pipe starts operating with the next VSYNC. If frame characteristics change however, (for example as in the case of the PPI's window feature), care is required to ensure that the PVP output (2-dimensional) DMAs match with the window settings every frame.

All block registers are double buffered. All coefficient registers can be written any time and are properly synchronized with pipe progress by hardware. However, the `PVP_XXX_CFG` registers must only be written when a pipe re-configuration is desired for the next set of frames. Writes to the `PVP_IPFx_CFG` registers need to be synchronized with ongoing activity.

**NOTE:** Register writes during daisy chain load period are not allowed. Writes are ignored and error bits are set. MMR reads incur 1 cycle of latency while writes incur no latency. Also note that access to holds/read only gives MMR error.

## Block Configuration Structure

The PVP can be programmed by writing to memory-mapped registers directly. However, an alternative configuration method using DMA channels can be used. This method is derived from the descriptor-based programming method of the DMA controllers themselves and works well with DMA programming.

The PVP features two configuration DMA inputs, one for camera pipe and one for memory pipe operation. These DMAs enable on-the-fly re-configuration of the two pipes independently. Each pipe can be configured or re-configured according to timing needs without core interaction.

The configuration DMA channels write to the MMR register space. For the processing blocks it does not make any difference whether a memory-mapped register has been written by a core write or by configuration DMA. Certainly, unlike core writes, configuration DMA's write timing is ensured by hardware and not subject of interrupt latencies.

The block configuration structure (BCS) is a telegram loaded by either of the configuration DMAs. It consists of a 32-bit block configuration header (BCH) which is followed by a number of 32-bit configuration words that target memory-mapped registers.

Figure 30-48: Block Configuration Structure

When the configuration DMA fetches a BCS, the BCH specifies the MMR destination of the subsequent configuration words. The 8-bit BCH.BLOCK field specifies which PVP processing block the subsequent configuration words belong to. This uses the same block id scheme as in. The 8-bit BCH.WOFF field specifies the word offset versus that first register of the block's register space. The 8-bit BCH.WCNT field specifies how many registers are to be written to the specified register space. The BCH.RESERVED field must be filled with zeros.

Configuration DMAs not only can fetch single BCSs, but also can fetch a series of BCSs at once. A series of BCHs is called block configuration list (BCL) and is illustrated in the following figure.

Figure 30-49: Block Configuration List Example

The example block configuration list consists of two BCSs. The first targets processing element CNV0. It contains three 32-bit configuration values to be written into three MMR registers that are contiguous in

register space. The register space contains multiple registers dedicated to the CNV0 block. Since the example BCS does not target the first three MMRs in CNV0 space, but rather the three from MMR2 on, the `BCH.WOFF` field is set to a value of 2. The second BCS target is CNV1. It only writes to a single register and since it is the first register in CNV1 space the `BCH.WOFF` field = 0.

## Initial Configuration Fetch

After the camera pipe or memory pipe have been enabled by the `PVP_CTL.PVPEN` or `PVP_CTL.CPEN` bits, the respective input formatter immediately requests a BCL fetch from the configuration DMA channel. If the configuration DMA does not grant the request because it is either not ready or not enabled, the pipe engine stalls until either the pipe is configured by MMR writes or the DMA starts granting. The IPFs do not accept any data on their data input until the pipe is fully configured and enabled.

When the configuration DMA is granted, the input formatters fetch BCL words until the `PVP_IPFx_CFG.START` bit is set. The BCL is assumed to describe a valid pipe configuration and to write a 1 to the `PVP_XXX_CFG.START` bits of all involved blocks. The `START` bit can be seen as a self-clearing block enable bit. The self-clearing nature of this bit ensures that software does not need to perform garbage collection at or after pipe re-configuration. Blocks that are no longer used are automatically disabled.

The `START` bits of the input formatters have additional purpose also enable the entire camera or memory pipe. Therefore, while the order of BCSs inside a BCL does not matter, only the very last BCS writes into the `PVP_IPF1_CFG` register.

Once the `PVP_IPFx_CFG.START` bit has been written, the IPF0 starts accepting data VSS, or IPF1 starts requesting data from data input DMA and the pipe starts processing.

## Descriptor-based Memory Pipe Configuration

To enable memory pipe operation, set the `PVP_CTL.PVPEN` and `PVP_CTL.MPEN` bits. Additionally, the `PVP_CTL.CLKDIV` must be configured properly. While the camera pipe is clocked by the data clock of the receiving PPI, the clock for the memory pipe is derived from system clock `SCLK0`. The PVP is designed for maximum operating frequency of 83MHz. For best performance:

- Clear `PVP_CTL.CLKDIV` if `SCLK0` <= 83.3 MHz, so the memory pipe clock equals `SCLK0`
- Set `PVP_CTL.CLKDIV` if `SCLK0` > 83.3 MHz, so memory pipe clock equals `SCLK0/2`

**NOTE:** Over clocking of memory pipe can lead to unpredictable behavior and thermal silicon defects.

Before enabling a memory pipe job, configure the respective data input and data output DMAs and enabled them immediately. Typically, the completion interrupt of the data output DMA is also enabled. It signals when the PVP memory pipe has completed the job and ensures that the results have been written back to memory.

A BCL structure is expected somewhere in system memory (L1, L2 or L3). This BCL structure can be statically pre configured or dynamically composed at run-time.

Finally, the configuration DMA is configured. The `DMAx_STARTADDR` registers point to the base address of the BCL. As soon as the configuration DMA is enabled the operation takes place autonomously. IPF1 starts requesting data from the data input DMA as soon as all BCL has been fetched, (once the `PVP_IPF1_CFG.START` bit has been set). Software is alerted by the completion interrupt of the data output DMA connected to OPF3.

## Dynamic Pipe Control

To control how a pipe behaves after it has been initially configured, the input formatters use the frame counter (`PVP_IPFx_FCNT`) registers. If these registers = 0, the respective pipe repeatedly operates in the same mode as long as it is not disabled by the `PVP_CTL.CPEN` or `PVP_CTL.MPEN` bit. If `FCNT = 1`, the pipe operates on exactly one frame and then stalls. If `FCNT` is set to a value of `N`, exactly `N` frames are processed.

If `FCNT = 0` or `FCNT = 1` the input formatters request a new BCL from configuration DMA every frame. If `FCNT > 1`, a new BCL is only requested every `N`th frame. Similarly, status reports can only be transmitted at `FCNT` frame boundaries.

Since the PVP is a pipelined engine, it takes `X + D` data clocks to process `X` data words, where `D` stands for the depth of the pipeline. The PVP is clocked by data and therefore, after `N` frames have been processed, a number of results (`D`) still stick in the pipe and do not yet progress to the data output DMA channel because the pipe is waiting for further BCL instructions. The first data clocks of the future operation then implicitly clock the older results out.

To automatically drain the remaining result words, set `DRAIN = 1`. This configuration allows IPF0 to pass further `D` data clocks into the pipe for this purpose. Keep Upstream PPI, PIXC and VSS (and video source device) enabled so they can provide the required clocks. However, IPF1 cannot rely on receiving further data clocks from data input DMA. Rather, if `DRAIN = 1`, IPF1 generates the required clocks itself artificially.

The `FCNT` and `DRAIN` bits partner in instructing the input formatter on how to control the pipe as shown in the following table.

**Table 30-29:** Operating Modes as by `FCNT` and `DRAIN`

| FCNT | DRAIN | Mode                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | 0     | <p>Mode 0: Continuous Frame Mode</p> <p>Frames are continuously requested by the IPFx and feed the PVP pipe. The Configuration DMA is constantly requesting BCL words every frame. If new Configuration is granted by DMA or by MMR writes, it is applied on the next frame boundary.</p> <p>Processing Blocks do not auto-disable. New Configuration must not set <code>PVP_xxx_CFG.START</code> bit of any block again.</p> |

**Table 30-29:** Operating Modes as by FCNT and DRAIN (Continued)

| FCNT | DRAIN | Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| >0   | 0     | <p>Mode 1: Back-to-Back Mode</p> <p>FCNT frames are requested by the IPFx and these feed the pipe. The last data words will be stuck in the pipe. Mode 0 is popular for camera pipe operation. Often, the camera pipe is enabled statically and updates to the coefficients is only required from time to time. On demand software may enable the configuration DMA in stop mode to trigger the fetch of one single BCL. In this mode the `PVP_IPFx_TAG` register is useful to match status results with a respective configuration. The new BCL only updates coefficients of processing blocks, it does not alter the pipe configuration.

Mode 1 is useful in camera pipe mode when coefficients have to change every Nth frame. It supports on-the-fly reprogramming of coefficients. However, it does not support on-the-fly reprogramming of pipe configurations. The following settings must not change unless the **DRAIN** bit is set:

- Pipe structure (`PVP_xxx_CFG` registers)
- Fundamental operating modes (like 1st derivative to 2nd derivative mode of PEC)
- Input format and OPORT configuration (`PVP_IPFx_CTL` registers)
- Horizontal size of input frame (**HCNT**)

If any of the above settings change on-the-fly, then the `DRAIN` bit must be set for proper operation. Mode 2 is used. In Memory Pipe mode the `DRAIN` bit causes of few clock cycles of overhead depending to pipeline depth. In camera pipe mode the `DRAIN` bit causes the loss of an entire frame. Operation stops after the pipe has been drained and resumes with the next incoming `VSYNC` signal.

Whenever the next PVP job stalls until the completion event of the data output DMA is flagged either as an interrupt or as a system trigger, setting the `DRAIN` bit is a requirement at the application level. The data output DMA work unit does not complete as long as related data sticks in the pipe. The data in the pipe does not progress until the configuration DMA and data source grant. Such deadlock situations can be avoided by using mode 2. Once a deadlock occurs, it can be resolved by mode 3 operation.

Mode 3 is more like a one-time instruction than an operating mode. It is used whenever software needs to respond to unpredicted events. For example, while the camera pipe is operating in mode 1, software notices that the future frames need to have alternating `HCNT` settings. If the pipe is already stalled waiting for new `BCL` instructions, a `BCL` containing a Drain Now instruction can gracefully switch the pipe from mode 1 into mode 2. All pending results in the pipe are still properly shifted out before the pipe resumes operation with the new `HCNT` settings after the subsequent `BCL` fetch.

The following list describes the difference between the modes in disabling the processing blocks after operation.

- In mode 1 the hardware only disables the input formatters after `FCNT` expires. All other blocks remain enabled. In principle, only the `PVP_IPFx_CFG` register needs to be rewritten to set the `START` bit again to initiate another operation. New configurations must not set the `START` bit of any other block another time. If a new write to the `PVP_XXX_CFG` register cannot be avoided, the `START` bit shall be written by a zero value.
- In mode 2 and mode 3 all blocks are disabled by hardware after the drain operation. For future operation rewrote the `PVP_XXX_CFG` register of all included blocks to set the `START` bit again.
- In mode 0 new configurations must not set the `START` bit of any block another time, not even the one of the input formatters. If a new write to the `PVP_XXX_CFG` register cannot be avoided, write the `START` bit to a zero value.

The `PVP_STAT` and `PVP_ILAT` registers report when the camera pipes (`CPDRN` bit) and the memory pipe (`MPDRN` bit) are drained. The ready bits, `PVP_STAT.CPRDY` and `PVP_STAT.MPRDY`, report whether `PVP_IPF0_CFG.START` and `PVP_IPF1_CFG.START` bits are ready to be set.

## Latency and Pipeline Depth

Most of PVP processing blocks have internal data buffers, if not row buffers. Before a first result can be generated, these buffers need to be filled with valid input data, so that the mathematical operation can be performed. The amount of buffers needed for the operation defines the latency that a block is adding to the chain if inserted into a pipe. This equals the number of artificial clocks that need to be applied in the case of a drain operation. Due to their 2-dimensional nature the `CNVx`, `PEC` and `UDS` blocks have local row buffers where they intermediately store one or multiple data rows. Consequently, their latency is much higher than that of the `IPFx`, `ACU`, `PMA` or `OPF` blocks. The `IIMx` block is special in that although it

performs 2-dimensional operations as well, it can generate outputs early, because results do not depend on future data.

**Table 30-30:** Block Latencies

| Processing Block | Latency [Data Clocks]                                                                 |
|------------------|---------------------------------------------------------------------------------------|
| IPFx             | 5                                                                                     |
| OPFx             | 1                                                                                     |
| THCx             | 3                                                                                     |
| CNVx             | 2x HCNT + 14                                                                          |
| PMA              | 5                                                                                     |
| ACU              | 7                                                                                     |
| PEC              | 2x HCNT + 11 if 2 <sup>nd</sup> derivative mode with ZCRSS=0,<br>otherwise 1xHCNT + 6 |
| IIMx             | 6                                                                                     |
| UDS              | varies with settings                                                                  |

## Daisy Chain Configuration

Configuration and coefficient MMRs of all processing blocks are double buffered. Whenever `FCNT` is zero and the `PVP_IPFx:CFG.START` bit = 1, the values are copied from MMR registers into application buffers at the frame boundary. Due to the pipelined nature of the PVP not all values are copied at the same time. Rather, the timing is closely related to how the `VSYNC` of the next frame progresses through the pipe. New settings apply to the first pixel of the new frame immediately after the last pixel of the old frame has been processed. The update command is daisy chained through the pipe, starting from the IPFx down to the OPFs.

While sequencing through the daisy chain operation, hardware clears the `PVP_xxx_CFG.START` bits of all involved processing blocks in MMR space. Write conflicts can occur if software attempts to write the `PVP_xxx_CFG` registers during the daisy chain.

The `PVP_STAT` register provides two status bits that report whether a daisy chain operation is ongoing in the camera pipes (`PVP_STAT.CPDC`) or in the memory pipe (`PVP_STAT.MPDC`). These bits are set along with the `PVP_IPFx_CFG.START` bit and are cleared if the output formatters have been updated.

In camera pipe mode the `CPDC` bit is cleared only after the daisy chain progresses through the furthest of the enabled OPFs. During this time, software should not write into PVP MMR space. If software mistak-

only does, this is reported by the `CPWRERR` and `MPWRERR` flags in the same register. While all status bits in the `PVP_STAT` register are self clearing, the `PVP_ILAT` register latches the events until cleared by a software handshake.

A block which is enabled in a given pipe, either camera or memory, can be moved to the other pipe only after the drain done command is received for the former pipe. This ensures that the module completely processes all the pixels in one pipe, and then is disabled before being re-enabled for pixel processing in the next pipe.

**NOTE:** Camera and memory pipes can be configured by MMR writes or BCL fetches. These are separate control mechanisms and are not intended to be mixed for a given pipe during ongoing operation. Before switching from one method to the other inspect the daisy chain and drain status bits in the `PVP_STAT` register to ensure no operation from the other method is pending.

## Job Lists

This section provides information on how to maintain lists of multiple operations for sequential processing (co-processor like mid-processing) by the PVP memory pipe (PVP memory pipe job list). Sequential processing requires minimal overhead for the core and has high PVP performance. The information this section also applies to the camera pipe.

In this section, data to be processed within the PVP memory pipe is assumed to be completely stored in memory. This is in contrast to the camera pipes in when processing data streams on the fly gated by an external (PIXEL) clock. In that case the processing data is not fully loaded into memory and additional measures are required to control the input data DMA so as not to run out of valid data. While this is technically possible it is not part of the following description.

This section requires basic knowledge of the DMA functionality, especially the use of linked list descriptors as well as 1-dimensional and 2-dimensional DMA operations. For more information, see the DMA and Trigger Routing chapters.

To sequentially schedule multiple PVP memory pipe operations, correctly initiate and trigger the following data flows (each handled by a different DMA move engine).

- DMA 45 moves the PVP memory pipe configuration (BCS block control structure list) of a specific PVP memory pipe job from memory into the PVP, configuring the processing functionality of the elements building the PVP memory pipe.
- DMA 43 moves the data set to be processed from memory into IPF1 using this specific PVP memory pipe configuration.
- DMA 42 moves the results of the PVP memory pipe operation (OPF3) to a destination, usually to memory.

The PVP can optionally generate an additional status (report) data stream originating from IPF1, THC0, or THC1. This data stream also needs to be moved from the PVP memory pipe status output to a destination, (usually to memory) using DMA 44.

To initiate the PVP memory pipe job list linked list, set up three DMA descriptors. Each linked descriptor stores the DMA configuration parameters within memory to maintain the DMA sequences to handle the three data flows, BCS, data IN, data OUT, and optionally status data OUT. If the descriptors are all completed by the core, multiple PVP memory pipe jobs can be chained without any further core intervention as the DMAs run through the chained lists and handle the multiple data flows autonomously. The following description assumes the memory pipe is inactive, (a non initialized state `PVP_CTL.MPEN = 0`).

## Configuration Descriptor List (Static Job List)

To run a PVP memory pipe job from the PVP memory pipe job list, the PVP first loads the memory pipe configuration into the respective shadow registers of the respective PCP elements to build the PVP memory pipe. The configuration within the shadow register is activated (transferred from shadow register to active register) using hardware triggers (staggered transfer). This configuration stream into the shadow registers is handled by DMA 45 which is controlled by a linked descriptor list. The last valid descriptor must contain a `DMA_CFG` field with `FLOW = 0` (STOP Mode) to gracefully stop the DMA 45 after completing the PVP memory pipe job list and avoid loading non valid data into PVP memory pipe configuration register. All `DMA_CFG` descriptor fields within the linked list have `FLOW = 6` or `FLOW = 7` (descriptor list mode) or alternatively `FLOW = 4` (descriptor array mode).

A 1-dimensional DMA operation is shown in the following figure. Note however, a 2-dimensional DMA operation can also be used.

**Figure 30-50:** Static Linked Descriptor List for Configuration Data (BCL Data)

## Global Trigger

After the first initialization of the linked descriptor list the parameter registers of DMA 45 have to be initialized, particularly the `DMA45_DSCPTR_NXT` and `DMA45_CFG` register. The DMA 45 is started but then stalls until the PVP memory pipe is enabled and the `IPF1_CFG` register bit field `FCNT` is equal to 0 (`FCNT = 0`).

To generate a unique synchronization signal that synchronizes the Data Out (DMA 42) and Data In (DMA 43) stream, all `DMA_CFG` descriptor fields of DMA 45 should have the bit field `TRIG` set (`TRIG = 1`). This generates a trigger signal after a new configuration is loaded into the shadow registers.

## Configuration Descriptor List (Dynamic Job List)

When the memory pipe job list is started before the creation of the PVP memory pipe job list is completed by the core (dynamic creation of PVP memory pipe jobs) the following issues must be considered.

- Use mode 1 (back-to-back mode) is for maximum performance. But because this mode moves data of a new job into the PVP memory pipe, while the data of the previous job has not been completely moved out of the PVP memory pipe due to memory pipe latency and the output buffer within OPF3, there must not be any data dependency between input and output data (no recursive data processing). Further the PVP memory pipe structure must not be modified, because the staggered loading of the configuration may not work correctly. A further challenge of this mode is the fact, that the last job cannot be completed, as it requires “dummy” data to be pushed explicitly into the PVP Memory Pipe to shift out the last results.
- Alternatively, dummy data (bubbles) may be implicitly (automatically) appended to every data set to entirely empty the PVP memory pipe before the new data are processed using mode 2 (auto-completion mode) of IPF1. Due to the bubbles moving through the PVP memory pipe, this mode decreases the performance of the PVP, but allows fully interlocked pipelined processing without the need for special care of control conflicts. Mixing both modes is usually not possible, because it requires dynamic modifications of the IPF1 configuration and DMA trigger configuration.

**NOTE:** Special care has to be exercised when using back-to-back mode if the PVP memory pipe job list has started before the creation of the PVP memory pipe job list has been completed by the core, or the data to be processed within the PVP memory pipe job list is not yet available in memory. Auto-completion mode is the preferable mode in these cases.

**NOTE:** Special care has to be exercised when the BCS includes PVP\_XXX\_CFG register updates, (with exception of PVP\_IPF1\_CFG). This requires processing the PVP memory pipe job list in mode 2 (auto-completion mode) as the staggered configuration load of the pipeline elements may no longer work correctly because the position of an element within the pipeline may change and therefore a different staggering order may be required

## Control Data Flow (Dynamic Job List, Auto-completion Mode and Back-to-Back Mode)

Support for dynamic job lists requires that the last valid descriptor (descriptor n) must contain a DMA\_CFG field with TWAIT = 1 (halt and wait for incoming trigger) instead of FLOW = 0 (stop mode) in order to pause and not stop the DMA channel and avoid loading non valid data (job creation not finalized) into the PVP memory pipe configuration register. An additional last descriptor (descriptor m) is reserved in memory, but only contains dummy values and a STOP mode in the DMA\_CFG field to handle erroneous descriptor overrun and enable dynamic memory allocation.

**Figure 30-51:** Linked Descriptor List for Configuration Data (BCL Data) Enabling Dynamic Extension

If adding an additional job to an existing PVP memory pipe job, this new job descriptor replaces the DUMMY descriptor (descriptor m) in memory. This updated descriptor m must now link to a new DUMMY descriptor (descriptor j).

**Figure 30-52:** Dynamic Extending Linked Descriptor List for Configuration Data (Job List)

After completing the descriptor m and the job list extension that handles Data In and Data Out, modify (clear) the `TWAIT` field of the `DMA_CFG` field of descriptor n. To grant a seamless DMA operation where:

- The DMA has already loaded the unmodified descriptor n:
- and has already copied the `TWAIT = 1` descriptor (original descriptor n) into the `DMA45_CFG` register:

Generate a software generated trigger for DMA 45 (and DMA 43 if in back-to-back mode). Therefore if `TWAIT = 1`, a trigger is generated within the trigger routing unit (TRU) by software.

Additionally, to grant a seamless DMA operation using auto-completion mode where:

- DMA 42 has already loaded the unmodified descriptor n:
- and therefore already copied the `TWAIT = 1` descriptor (descriptor n) into the `DMA42_CFG` register:

Generate a software generated trigger for DMA 43. Therefore if `TWAIT = 1`, a trigger is generated within the TRU by software.

Take special care if writing the `TWAIT` field of the `DMA_CFG` field and if reading the `DMA45_CFG` and `DMA42_CFG` registers takes longer than the DMA operation loading the configuration data.

**NOTE:** Alternatively, instead of setting `TWAIT = 1`, use `FLOW = 0` as a semaphore (STOP MODE). Set the `DMA45_CFG` register (write operations) to descriptor mode if the DMA stopped.

## Data Out Flow (Static Job List)

After successfully setting up and starting the DMA 45 linked descriptor list for the configuration data of the PVP memory pipe, set up an additional DMA (DMA 42) to move Data Out (result data) from the PVP memory pipe (out of OPF3) into memory. A second linked descriptor list that handles the output data (result) is set up according to the previous description of the `DMA_45` linked description list. Optionally set up DMA 44 using an additional linked descriptor list that handles Status Data Out.

These data streams, the Data Out and the Status Data Out, are handled by dedicated DMAs. DMA 42 handles the Data Out stream and DMA 44 the Status Data Out stream.

Both are controlled by their respective linked descriptor list. The last valid descriptor of each linked list must contain a `DMA_CFG` field having a `FLOW = 0` (STOP Mode) to gracefully stop the DMA 42 and (optionally) DMA 45 after completing the PVP memory pipe job list and to avoid loading non valid data into PVP memory pipe configuration register. All `DMA_CFG` descriptor fields within the linked list have `FLOW = 6` or `FLOW = 7` (descriptor mode) or alternatively `FLOW = 4` (descriptor array mode). Configure the TRU to route the trigger of DMA 45 to the input trigger of DMA 42 and DMA 44.

**Figure 30-53:** Static Linked Descriptor List for Data OUT (Result Data) and Optionally Status Data Out

## Data Out Flow (Dynamic Job List)

The following situations describe handling Data Out data streams using back-to-back mode or auto-completion mode. Mixing modes is not possible because it requires modifications of the IPF1 configuration and the DMA trigger configuration.

- Use mode 1 (back-to-back mode) for maximum performance. Note that this mode moves data to be processed by a new job into the IPF1 while the resulting data processed by the previous job has not been completely moved out of the PVP memory pipe. This is because there may not be any data dependency between the input and output data (recursive data processing) in the output buffer within OPF3, as well as PVP memory pipe latency. Further, the PVP memory pipe structure may not be modified because the staggered loading of the configuration may not work correctly. A further challenge of this mode is

it requires “dummy” data to be pushed explicitly into the PVP memory pipe to shift out the last results and therefore the last job cannot be completed.

- Use mode 2 (auto-completion mode) for fully interlocked pipelined processing without care for data hazards (read after write hazard). This mode appends dummy data (bubbles) implicitly (automatically) to every data set to empty the PVP memory pipe before the new data is processed in IPF1. Because the bubbles move through the PVP memory pipe, this mode decreases the performance of the PVP.

Special care must be exercised when using back-to-back mode if the PVP memory pipe job list has been started before the creation of the PVP memory pipe job list has been completed by the core, or if the data to be processed within the PVP memory pipe job list is not yet available in memory. Auto-completion mode should be used in these cases.

## Data Out Flow (Dynamic Job List, Back-to-back Mode)

Dynamic job lists require that the last valid descriptor (descriptor n) for DMA 42 (and optionally DMA 44) to contain a `DMA_CFG` field with `TWAIT = 1` (halt and wait for incoming trigger). This is so the DMA channel pauses instead of stops, and avoids loading non valid data (job creation not finalized) into the PVP memory pipe configuration register. An additional last descriptor (descriptor m) is reserved in memory which contains dummy values and a `FLOW = 0` (STOP mode) in the `DMA_CFG` field to handle erroneous overrun.

If adding an additional job to an existing PVP memory pipe job, the new job descriptor replaces the DUMMY descriptor (descriptor m) in memory. This updated descriptor m must now link to a new DUMMY descriptor (descriptor j).

**Figure 30-54:** Linked Descriptor List for Data OUT (Results) Enabling Dynamic Extension (Back-to-Back Mode)

After completing the descriptor m and the job list extension to Data In and Data Out, clear the `TWAIT` field of the `DMA_CFG` field of descriptor n.

**Figure 30-55:** Dynamic Extending Linked Descriptor List for Data OUT (Job List) in Back-to-Back Mode

## Data Out Flow (Dynamic Job List, Auto-Completion Mode)

In auto-completion mode the DMA handling the Data Out (DMA 42) triggers (synchronizes) the DMA handling the Data In (DMA 43). Therefore DMA 42 has to generate a respective trigger. Configure the TRU to route the trigger of DMA 42 to the input trigger of DMA 43.

All descriptors must have `TRIG = 1` in the `DMA_CFG` field to enable trigger generation. Only the last valid descriptor has `TRIG = 0` in the `DMA_CFG` field which puts the DMA 43 into pause state.

**Figure 30-56:** Linked Descriptor List for Data OUT (Results) Enabling Dynamic Extension (Auto-Completion Mode)

If adding an additional job to an existing PVP memory pipe job, this new job descriptor replaces the DUMMY descriptor (descriptor m) in memory. This updated descriptor m must now link to a new DUMMY descriptor (descriptor j).

After completing the descriptor m and the job list extension to Data In and Data Out, change the `TRIG` setting of descriptor n to `TRIG = 1`.

**Figure 30-57:** Dynamic Extending Linked Descriptor List for Data OUT (Job List) in Auto-Completion Mode

## Data In Descriptor List (Static Job List)

After successfully setting up and starting DMA 42, DMA 45, and (optionally) DMA 44, set up the DMA 43 linked descriptor list for the input data (Data In) to be moved into IPF1.

A third linked descriptor list that handles the Data In is set up according to the previous description of the DMA\_42 linked description list. This data stream is handled by a dedicated DMA (DMA 43) which is controlled by a linked descriptor list. The last valid descriptor of the linked list must contain a DMA\_CFG field with `FLOW = 0` (STOP Mode) to gracefully stop the DMA 43 after completing the PVP memory pipe job List and avoid loading non valid data into PVP Memory Pipe configuration register. All DMA\_CFG descriptor fields within the linked list have `FLOW = 6` or `FLOW = 7` (descriptor list mode) or alternatively `FLOW = 4` (descriptor array mode). Configure the TRU to route the trigger of DMA 45 (back-to-back mode) or DMA 42 (auto-completion mode) to input trigger of DMA 43. All DMA\_CFG descriptor field must therefore have a `TWAIT` field set (`TWAIT = 1`).

**Figure 30-58:** Static Linked Descriptor List for Data IN

## Data In Flow (Dynamic Job List)

Dynamic job lists require that the last valid descriptor (descriptor n) for DMA 43 contain a DMA\_CFG field having a `TWAIT = 1` (halt and wait for incoming trigger) instead of `FLOW = STOP`. This is so the DMA channel pauses instead of stops, and avoids loading non valid data (job creation not finalized) into the PVP memory pipe configuration register. An additional last descriptor (descriptor m) is reserved in memory

which contains dummy values and a `FLOW = 0` (STOP mode) in the `DMA_CFG` field to handle erroneous over-runs.

**Figure 30-59:** Linked Descriptor List for Data IN Enabling Dynamic Extension

If adding an additional job to an existing PVP memory pipe job, this new job descriptor has to replace the DUMMY descriptor (descriptor m) in memory. This updated descriptor m must now link to a new DUMMY descriptor (descriptor j).

Auto-completion mode and back-to-back mode require identical Data Out descriptor list.

**Figure 30-60:** Dynamic Extending Linked Descriptor List for Data IN

## Starting a Job List

After setting up the three DMA linked lists, the memory pipe has to be activated (`PVP_CTL.MPEN = 1`).

## Data Flow (Static Job List, Back-to-Back Mode)

The following figure shows the data flow using a static job list and back-to-back mode.

The DMA45 generates a trigger for DMA 43 and DMA 42. DMA45 in return is triggered by the memory pipe requesting a new configuration. In this case the PVP memory pipe is enabled and the `IPF1_CFG` register bit field `FCNT = 0` (memory pipe request).

**Figure 30-61:** Static Job List Data Flow (Back-to-Back Mode)

## Data Flow (Static Job List, Auto completion Mode)

The following figure and procedure shows the data flow using a static job list and auto-completion mode.

1. DMA45 generates a trigger for DMA 43
2. DMA 43 generates a trigger for DMA 42
3. Software generates the first trigger for DMA 42
4. DMA45 is triggered when the memory pipe requests a new configuration. In this case the PVP memory pipe is enabled and the `IPF1_CFG` register bit field `FCNT = 0` (memory pipe request)

**Figure 30-62:** Static Job List Data Flow (Auto-Completion Mode)

**Data Flow (Dynamic Job List, Back-to-Back Mode)**

The following figure shows the data flow using a dynamic job list and back-to-back mode. This figure illustrates that job creation processed by the CPU is slower than the PVP. The PVP reaches the end of the valid job list before the CPU generates a new job.

The software reads  $TWAIT$  of DMA45 and as a consequence generates a trigger by software to start the new job in DMA45.

**Figure 30-63:** Dynamic Job List Data Flow (Back-to-Back Mode)

## Data Flow (Dynamic Job List, Auto-Completion)

The following figure shows the data flow using a dynamic job list and auto-completion mode. This figure and procedure demonstrate that job creation processed by the CPU is slower than the PVP processing the valid job list. Therefore, the PVP reaches the end of the valid job list before the CPU generates a new job.

1. The software reads `TWAIT` of DMA45 and as a consequence generates a trigger to start the new job in DMA45.
2. The software then reads `TWAIT` of DMA43 and as a consequence generates a trigger to start the new job in DMA42.

**Figure 30-64:** Dynamic Job List Data Flow (Auto-Completion Mode)

## Status (Histogram) Reports

Beside the PVP\_STAT register, which flags synchronization events and errors, the PVP also provides an automatic method to output status reports (primarily to output the histogram results). The THCx blocks latch the status of their histogram counters into MMR space every frame. Software can rely on histogram ready events as signaled by the PVP\_STAT.THCxRDY status flags and then manually collect the numerous MMR registers. To ensure consistency of the reports the MMR reads can be performed by an atomic procedure ensuring interrupts cannot interfere.

The PVP features two status output DMA channels that output the histogram reports more easily. Once configured and enabled, the status DMA operate independently from software. Report Consistency and proper read-out timing is ensured by hardware.

One status DMA is associated with the camera pipe, and one with the memory pipe. The feature is enabled by the `PVP_IPFx_PIECTL.STATEN` control bits. If enabled, a status report is sent every time `PVP_IPFx_FCNT` counts to zero. If `PVP_IPFx_FCNT` has been programmed to zero, the report is sent after every frame.

If PVP configuration is frequently updated on the fly, system software might be exposed to risk to lose track of which configuration a specific report belongs to. For this purpose the input formatters feature the `PVP_IPFx_TAG` registers. At configuration time any 16-bit tag can be loaded into these registers. If `PVP_IPFx_FCNT` expires the tag value progresses to the `PVP_IPFx_TAG_STAT` counterpart register in the MMR space. It can then optionally be stored via DMA paired with the histogram results.

## Status Word Counters

When a report is sent to status output DMA the content of the report can be structured by the program. Only the IPFx and THCx modules can contribute to the report as follows.

- IPF0 can send only to camera pipe status DMA
- IPF1 only can send to memory pipe status DMA
- THC0 and THC1 always send the status to the status DMA of the pipe they belong to

If the `PVP_IPFx_PIECTL.STATEN` status enable bit is set, the `PVP_IPFx_CFG.STATWCNT` field controls how many status words the respective input formatter sends to the status channel. Since the input formatters feature only one status word contained in the `PVP_IPFx_TAG_STAT` register, only two values are valid for the `PVP_IPFx_CFG.STATWCNT` field. If `=0`, the input formatter does not contribute to the status report. If `=1`, the input formatter sends one 32-bit word, the 32-bit padded `PVP_IPFx_TAG_STAT` register to the status channel.

**NOTE:** Since the `STATWCNT` field resides in the `PVP_IPFx_CFG` register, its value cannot be altered without setting the `DRAIN` bit `=1`. The `STATEN` bit, however, resides in the same register as the `DRAIN` bit. Therefore, the structure of the status report must not change while `DRAIN = 0`. However, `STATWCNT` is allowed to alter the `STATEN` bit with every configuration, even when `DRAIN = 0`.

The threshold blocks feature many more status registers. Each features one histogram frame counter plus 16 histogram counters (`PVP_THCx_HCNT0_STAT` to `PVP_THCx_HCNT15_STAT`) plus one `PVP_THCx_RREP_STAT` register that holds the number of run-length reports per frame.

- If the `PVP_THCx_CFG.STATWCNT` field `=0`, the respective threshold block does not contribute to the status report.
- If `STATWCNT = 1`, only the `PVP_THCx_FCNT_STAT` is sent.
- If `STATWCNT = 9`, then `PVP_THCx_HCNT0_STAT` to `PVP_THCx_HCNT7_STAT` registers are sent on top of `PVP_THCx_FCNT_STAT`.
- If `=17`, then the `PVP_THCx_FCNT_STAT` register plus all 16 histogram values are sent.
- If 18, then all 18 status registers of the Threshold block are sent.

The `STATWCNT` field of all processing blocks other than IPFs and THCs are reserved and must be initialized with zero values.

Status reports only output status registers. There is no programmable offset as in the case of block configuration.

## Block Status Structure

When a processing block contributes to a status report, its data words are headed by a block status header (BSH). The BSH is similar to the block configuration header (BCH). It consists of the block ID value and also has a word count field. The latter mirrors the `STATWCNT` value as specified in the block configuration register. Unlike BCHs the BSHs don't have an offset field. The entity of Block Status Header and respective status words is called Block Status Structure (BSS). A BSS always consists of `STATWCNT+1` 32-bit words.

A status report consists of a list of block status structures. Such a list is referred to as block status list (BSL). An example is shown in the following figure. It assumes that both threshold blocks are configured in camera pipe mode. IPF0 and THC0 are configured to send status to the report, THC1 is not and its `STATWCNT` field =0.

**Figure 30-65:** BSL Example

The input formatters make always the first entries in the block status list. If both threshold blocks are enabled in the same pipe, the one that comes first is closer to the IPFx in the pipe arrangement. In case the pipe configuration is not known, the block ID in the BSHs can be consulted.

Although it is not a hardware requirement, it is recommended that the work unit transfer count of the DMA associated with the status output matches the number of 32-bit words in the BSL.

## PVP Register Descriptions

PVP (PVP) contains the following registers.

**Table 30-31:** PVP Module Registers

| Name               | Description                        |
|--------------------|------------------------------------|
| PVP_REVID          | Revision ID                        |
| PVP_CTL            | Control                            |
| PVP_IMSKn          | Interrupt Mask n                   |
| PVP_STAT           | Status                             |
| PVP_ILAT           | Interrupt Latch Status n           |
| PVP_IREQn          | Interrupt Request n                |
| PVP_OPFn_CFG       | OPFn (Camera Pipe) Configuration   |
| PVP_OPFn_CTL       | OPFn (Camera Pipe) Control         |
| PVP_OPF3_CFG       | OPF3 (Memory Pipe) Configuration   |
| PVP_OPF3_CTL       | OPF3 (Memory Pipe) Control         |
| PVP_PEC_CFG        | PEC Configuration                  |
| PVP_PEC_CTL        | PEC Control                        |
| PVP_PEC_D1TH0      | PEC Lower Hysteresis Threshold     |
| PVP_PEC_D1TH1      | PEC Upper Hysteresis Threshold     |
| PVP_PEC_D2TH0      | PEC Weak Zero Crossing Threshold   |
| PVP_PEC_D2TH1      | PEC Strong Zero Crossing Threshold |
| PVP_IIMn_CFG       | IIMn Configuration                 |
| PVP_IIMn_CTL       | IIMn Control                       |
| PVP_IIMn_SCALE     | IIMn Scaling Values                |
| PVP_IIMn_SOVF_STAT | IIMn Signed Overflow Status        |

**Table 30-31:** PVP Module Registers (Continued)

| Name               | Description                                |
|--------------------|--------------------------------------------|
| PVP_IIMn_UOVF_STAT | IIMn Unsigned Overflow Status              |
| PVP_ACU_CFG        | ACU Configuration                          |
| PVP_ACU_CTL        | ACU Control                                |
| PVP_ACU_OFFSET     | ACU SUM Constant                           |
| PVP_ACU_FACTOR     | ACU PROD Constant                          |
| PVP_ACU_SHIFT      | ACU Shift Constant                         |
| PVP_ACU_MIN        | ACU Lower Sat Threshold Min                |
| PVP_ACU_MAX        | ACU Upper Sat Threshold Max                |
| PVP_UDS_CFG        | UDS Configuration                          |
| PVP_UDS_CTL        | UDS Control                                |
| PVP_UDS_OHCNT      | UDS Output HCNT                            |
| PVP_UDS_OVCNT      | UDS Output VCNT                            |
| PVP_UDS_HAVG       | UDS HAVG                                   |
| PVP_UDS_VAVG       | UDS VAVG                                   |
| PVP_IPF0_CFG       | IPF0 (Camera Pipe) Configuration           |
| PVP_IPFn_PIECTL    | IPFn (Camera/Memory Pipe) Pipe Control     |
| PVP_IPFn_CTL       | IPFn (Camera/Memory Pipe) Control          |
| PVP_IPFn_TAG       | IPFn (Camera/Memory Pipe) TAG Value        |
| PVP_IPFn_FCNT      | IPFn (Camera/Memory Pipe) Frame Count      |
| PVP_IPFn_HCNT      | IPFn (Camera/Memory Pipe) Horizontal Count |
| PVP_IPFn_VCNT      | IPFn (Camera/Memory Pipe) Vertical Count   |
| PVP_IPF0_HPOS      | IPF0 (Camera Pipe) Horizontal Position     |

**Table 30-31:** PVP Module Registers (Continued)

| Name              | Description                          |
|-------------------|--------------------------------------|
| PVP_IPF0_VPOS     | IPF0 (Camera Pipe) Vertical Position |
| PVP_IPFn_TAG_STAT | IPFn (Camera/Memory Pipe) TAG Status |
| PVP_IPF1_CFG      | IPF1 (Memory Pipe) Configuration     |
| PVP_CNVn_CFG      | CNVn Configuration                   |
| PVP_CNVn_CTL      | CNVn Control                         |
| PVP_CNVn_C00C01   | CNVn Coefficients 0,0 and 0,1        |
| PVP_CNVn_C02C03   | CNVn Coefficients 0,2 and 0,3        |
| PVP_CNVn_C04      | CNVn Coefficient 0,4                 |
| PVP_CNVn_C10C11   | CNVn Coefficients 1,0 and 1,1        |
| PVP_CNVn_C12C13   | CNVn Coefficients 1,2 and 1,3        |
| PVP_CNVn_C14      | CNVn Coefficient 1,4                 |
| PVP_CNVn_C20C21   | CNVn Coefficients 2,0 and 2,1        |
| PVP_CNVn_C22C23   | CNVn Coefficients 2,2 and 2,3        |
| PVP_CNVn_C24      | CNVn Coefficient 2,4                 |
| PVP_CNVn_C30C31   | CNVn Coefficients 3,0 and 3,1        |
| PVP_CNVn_C32C33   | CNVn Coefficients 3,2 and 3,3        |
| PVP_CNVn_C34      | CNVn Coefficient 3,4                 |
| PVP_CNVn_C40C41   | CNVn Coefficients 4,0 and 4,1        |
| PVP_CNVn_C42C43   | CNVn Coefficients 4,2 and 4,3        |
| PVP_CNVn_C44      | CNVn Coefficient 4,4                 |
| PVP_CNVn_SCALE    | CNVn Scaling Factor                  |
| PVP_THCn_CFG      | THCn Configuration                   |

**Table 30-31:** PVP Module Registers (Continued)

| Name             | Description                |
|------------------|----------------------------|
| PVP_THCn_CTL     | THCn Control               |
| PVP_THCn_HFCNT   | THCn Histogram Frame Count |

| PVP_THCn_HCNT4_STAT  | THCn Histogram Counter Value 4     |
| PVP_THCn_HCNT5_STAT  | THCn Histogram Counter Value 5     |
| PVP_THCn_HCNT6_STAT  | THCn Histogram Counter Value 6     |
| PVP_THCn_HCNT7_STAT  | THCn Histogram Counter Value 7     |
| PVP_THCn_HCNT8_STAT  | THCn Histogram Counter Value 8     |
| PVP_THCn_HCNT9_STAT  | THCn Histogram Counter Value 9     |
| PVP_THCn_HCNT10_STAT | THCn Histogram Counter Value 10    |
| PVP_THCn_HCNT11_STAT | THCn Histogram Counter Value 11    |

Table 30-31: PVP Module Registers (Continued)

| Name                 | Description                     |
|----------------------|---------------------------------|
| PVP_THCn_HCNT12_STAT | THCn Histogram Counter Value 12 |
| PVP_THCn_HCNT13_STAT | THCn Histogram Counter Value 13 |
| PVP_THCn_HCNT14_STAT | THCn Histogram Counter Value 14 |
| PVP_THCn_HCNT15_STAT | THCn Histogram Counter Value 15 |
| PVP_THCn_RREP_STAT   | THCn Number of RLE Reports      |
| PVP_PMA_CFG          | PMA Configuration               |

Revision ID

The PVP\_REVID register provides the PVP module revision information.

Figure 30-66: PVP\_REVID Register Diagram

Table 30-32: PVP\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration           |
|---------|----------|-----------------------------------|
| 7:4     | MAJOR    | Major ID.                         |
| 3:0     | REV      | Revision ID for a given Major ID. |

Control

The PVP\_CTL register provides enables the module, enables the memory pipe, enables the camera pipe, and selects the SCLK0-to-PVPCLK clock divisor. Note that PVP\_CTL.PVPEN, PVP\_CTL.MPEN, and/or

PVP\_CTL.CPEN disable and re-enable MUST be followed by a fresh write of all required values in all shadow registers.

**PVP\_CTL: Control - R/W**

Reset = 0x0000 0000

|---------|-----------|-----------------------------------------------------------------------------------------------------------------|
| 25      | ACUOUTSAT | ACU MIN/MAX Saturate Unmask.<br>The PVP_IMSKn.ACUOUTSAT bit enables/disables the PVP_IMSKn.ACUOUTSAT interrupt. |
| 24      | ACUDIVERR | ACU Divide By Zero Unmask.<br>The PVP_IMSKn.ACUDIVERR bit enables/disables the PVP_IMSKn.ACUDIVERR interrupt.   |
| 23      | IIM1SOVF  | IIM1 Signed Overflow Unmask.<br>The PVP_IMSKn.IIM1SOVF bit enables/disables the PVP_IMSKn.IIM1SOVF interrupt.   |
| 22      | IIM1UOVF  | IIM1 Unsigned Overflow Unmask.<br>The PVP_IMSKn.IIM1UOVF bit enables/disables the PVP_IMSKn.IIM1UOVF interrupt. |
| 21      | IIM0SOVF  | IIM0 Signed Overflow Unmask.<br>The PVP_IMSKn.IIM0SOVF bit enables/disables the PVP_IMSKn.IIM0SOVF interrupt.   |
| 20      | IIM0UOVF  | IIM0 Unsigned Overflow Unmask.<br>The PVP_IMSKn.IIM0UOVF bit enables/disables the PVP_IMSKn.IIM0UOVF interrupt. |
| 18      | THC1RDY   | THC1 Report Ready Unmask.<br>The PVP_IMSKn.THC1RDY bit enables/disables the PVP_IMSKn.THC1RDY interrupt.        |
| 16      | THC0RDY   | THC0 Report Ready Unmask.<br>The PVP_IMSKn.THCORDY bit enables/disables the PVP_IMSKn.THCORDY interrupt.        |
| 15      | MPRDY     | Memory Pipe Ready Unmask.<br>The PVP_IMSKn.MPRDY bit enables/disables the PVP_IMSKn.MPRDY interrupt.            |
| 14      | CPRDY     | Camera Pipe Ready Unmask.<br>The PVP_IMSKn.CPRDY bit enables/disables the PVP_IMSKn.CPRDY interrupt.            |
| 13      | MPDRN     | Memory Pipe Drain Done Unmask.<br>The PVP_IMSKn.MPDRN bit enables/disables the PVP_IMSKn.MPDRN interrupt.       |

**Table 30-34:** PVP\_IMSKn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------|
| 12      | CPDRN    | Camera Pipe Drain Done Unmask.<br>The PVP_IMSKn.CPDRN bit enables/disables the PVP_IMSKn.CPDRN interrupt.          |
| 10      | CPIPF0VF | Camera Pipe Pixel Overrun Unmask.<br>The PVP_IMSKn.CPIPF0VF bit enables/disables the PVP_IMSKn.CPIPF0VF interrupt. |
| 9       | MPOPFDAT | Memory Pipe First Pixel Unmask.<br>The PVP_IMSKn.MPOPFDAT bit enables/disables the PVP_IMSKn.MPOPFDAT interrupt.   |
| 8       | CPOPFDAT | Camera Pipe First Pixel Unmask.<br>The PVP_IMSKn.CPOPFDAT bit enables/disables the PVP_IMSKn.CPOPFDAT interrupt.   |
| 7       | CPSTOVF  | Status DDE Stall Error Unmask.<br>The PVP_IMSKn.CPSTOVF bit enables/disables the PVP_IMSKn.CPSTOVF interrupt.      |
| 6       | OPF2OVF  | OPF2 DDE Stall Error Unmask.<br>The PVP_IMSKn.OPF2OVF bit enables/disables the PVP_IMSKn.OPF2OVF interrupt.        |
| 5       | OPF1OVF  | OPF1 DDE Stall Error Unmask.<br>The PVP_IMSKn.OPF1OVF bit enables/disables the PVP_IMSKn.OPF1OVF interrupt.        |
| 4       | OPF0OVF  | OPF0 DDE Stall Error Unmask.<br>The PVP_IMSKn.OPF0OVF bit enables/disables the PVP_IMSKn.OPF0OVF interrupt.        |
| 3       | MPWRERR  | Memory Pipe MMR Write Error Unmask.<br>The PVP_IMSKn.MPWRERR bit enables/disables the PVP_IMSKn.MPWRERR interrupt. |
| 2       | CPWRERR  | Camera Pipe MMR Write Error Unmask.<br>The PVP_IMSKn.CPWRERR bit enables/disables the PVP_IMSKn.CPWRERR interrupt. |
| 1       | MPDC     | Memory Pipe DC Unmask.<br>The PVP_IMSKn.MPDC bit enables/disables the PVP_IMSKn.MPDC interrupt.                    |

**Table 30-34:** PVP\_IMSKn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                         |
|---------|----------|-------------------------------------------------------------------------------------------------|
| 0       | CPDC     | Camera Pipe DC Unmask.<br>The PVP_IMSKn.CPDC bit enables/disables the PVP_IMSKn.CPDC interrupt. |

## Status

The PVP\_STAT register indicates whether or not a PVP status related interrupts is pending. For all PVP\_STAT bits, a set bit indicates a pending interrupt, and a cleared bit indicates that no interrupt is pending. The bits in this register are automatically set or cleared by changes to PVP status, and all bits are read-only.

# PVP\_STAT: Status - R/NW

Reset = 0x0000 c000

Figure 30-69: PVP\_STAT Register Diagram

**Table 30-35:** PVP\_STAT Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                                                      |                      |
|---------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| 27      | ACUSUMSAT  | ACU SUM Saturate Status.<br>The PVP_STAT.ACUSUMSAT bit indicates whether or not the PVP_STAT.ACUSUMSAT interrupt is pending. This interrupt is set by an ACU on a frame boundary having sum saturation, and this interrupt is cleared on the next frame boundary.            |                      |
|         |            | 0                                                                                                                                                                                                                                                                            | No Pending Interrupt |
|         |            | 1                                                                                                                                                                                                                                                                            | Pending Interrupt    |
| 26      | ACUPRODSAT | ACU PROD Saturate Status.<br>The PVP_STAT.ACUPRODSAT bit indicates whether or not the PVP_STAT.ACUPRODSAT interrupt is pending. This interrupt is set by an ACU on a frame boundary having product saturation, and this interrupt is cleared on the next frame boundary.     |                      |
|         |            | 0                                                                                                                                                                                                                                                                            | No Pending Interrupt |
|         |            | 1                                                                                                                                                                                                                                                                            | Pending Interrupt    |
| 25      | ACUOUTSAT  | ACU MIN/MAX Saturate Status.<br>The PVP_STAT.ACUOUTSAT bit indicates whether or not the PVP_STAT.ACUOUTSAT interrupt is pending. This interrupt is set by an ACU on a frame boundary having min or max saturation, and this interrupt is cleared on the next frame boundary. |                      |
|         |            | 0                                                                                                                                                                                                                                                                            | No Pending Interrupt |
|         |            | 1                                                                                                                                                                                                                                                                            | Pending Interrupt    |
| 24      | ACUDIVERR  | ACU Divide By Zero Status.<br>The PVP_STAT.ACUDIVERR bit indicates whether or not the PVP_STAT.ACUDIVERR interrupt is pending. This interrupt is set by an ACU on a frame boundary having div by zero error, and this interrupt is cleared on the next frame boundary.       |                      |
|         |            | 0                                                                                                                                                                                                                                                                            | No Pending Interrupt |
|         |            | 1                                                                                                                                                                                                                                                                            | Pending Interrupt    |

## Interrupt Latch Status n

The PVP\_ILAT register indicates that latched status of interrupts for the PVP. For all PVP\_ILAT bits, a set the bit indicates that the interrupt has occurred, and cleared bit indicates that the interrupt has not occurred. The bits in PVP\_ILAT are set by PVP status, but are cleared with a write-1-to-clear operation. Note that clearing a bit in PVP\_ILAT clears the corresponding bit in the PVP\_IREQn register.

**PVP\_ILAT: Interrupt Latch Status n - R/W**

Reset = 0x0000 c000

**Figure 30-70: PVP\_ILAT Register Diagram**

**Table 30-36: PVP\_ILAT Register Fields**

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                     |

|         |          | 1                                                                                                                                                                            | Interrupt Latched |
| 0       | CPDC     | Camera Pipe DC Latch.<br>The <code>PVP_ILAT.CPDC</code> bit indicates that the <code>PVP_ILAT.CPDC</code> has occurred. Write 1 to clear this status bit.                    |                   |
|         |          | 1                                                                                                                                                                            | Interrupt Latched |

## Interrupt Request n

The `PVP_IREQn` register contains the latched interrupt request status. These requests reflect the status of interrupts that are latched in the `PVP_ILAT` register and are unmasked (enabled) in the `PVP_IMSKn`. The `PVP_IREQn` bits are set by PVP status, but cleared through a write-1-to-clear operation. Note that clearing a bit in `PVP_IREQn` clears the corresponding bit in the `PVP_ILAT` register.

PVP\_IREQn: Interrupt Request n - R/W

Reset = 0x0000 0000

Figure 30-71: PVP\_IREQn Register Diagram

Table 30-37: PVP\_IREQn Register Fields

| Bit No. | Bit Name   | Description/Enumeration    |
|---------|------------|----------------------------|
| 27      | ACUSUMSAT  | ACU SUM Saturate Request.  |
|         |            | 1 Unmasked Int Req Latched |
| 26      | ACUPRODSAT | ACU PROD Saturate Request. |
|         |            | 1 Unmasked Int Req Latched |

**Table 30-37:** PVP\_IREQn Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration         |                          |
|---------|-----------|---------------------------------|--------------------------|
| 25      | ACUOUTSAT | ACU MIN/MAX Saturate Request.   |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 24      | ACUDIVERR | ACU Divide By Zero Request.     |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 23      | IIM1SOVF  | IIM1 Signed Overflow Request.   |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 22      | IIM1UOVF  | IIM1 Unsigned Overflow Request. |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 21      | IIM0SOVF  | IIM0 Signed Overflow Request.   |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 20      | IIM0UOVF  | IIM0 Unsigned Overflow Request. |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 18      | THC1RDY   | THC1 Report Ready Request.      |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 16      | THC0RDY   | THC0 Report Ready Request.      |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 15      | MPRDY     | Memory Pipe Ready Request.      |                          |
|         |           | 1                               | Unmasked Int Req Latched |
| 14      | CPRDY     | Camera Pipe Ready Request.      |                          |

|         |          | 1 Unmasked Int Req Latched |

OPFn (Camera Pipe) Configuration

The output data formatter (OPF) blocks house FIFOs that buffer data for a sustained peak bandwidth output. The PVP\_OPFn\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

**PVP\_OPFn\_CFG: OPFn (Camera Pipe) Configuration - R/W**

Reset = 0x0000 0000

# OPF3 (Memory Pipe) Configuration

The output data formatter (OPF) blocks house FIFOs that buffer data for a sustained peak bandwidth output. The PVP\_OPF3\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_OPF3\_CFG: OPF3 (Memory Pipe) Configuration - R/W

Reset = 0x0000 0004

PEC Configuration

The pixel edge classifier (PEC) block performs pre-processing for the first derivative canny edge detection algorithm. The PVP\_PEC\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_PEC\_CFG: PEC Configuration - R/W

Reset = 0x0000 0000

|---------|----------|-----------------------------|
| 15:0    | VALUE    | Upper Hysteresis Threshold. |

## PEC Weak Zero Crossing Threshold

The PVP\_PEC\_D2TH0 provides an upper threshold that the PEC uses to remove the noise during weak zero crossing detection. Zero crossings are considered valid only if there is a sign change and id the difference between the 2nd derivative values of these two pixels is greater than the threshold.

PVP\_PEC\_D2TH0: PEC Weak Zero Crossing Threshold - R/W

Reset = 0x0000 0000

Figure 30-80: PVP\_PEC\_D2TH0 Register Diagram

Table 30-46: PVP\_PEC\_D2TH0 Register Fields

| Bit No. | Bit Name | Description/Enumeration       |
|---------|----------|-------------------------------|
| 14:0    | VALUE    | Weak Zero Crossing Threshold. |

## PEC Strong Zero Crossing Threshold

The PVP\_PEC\_D2TH1 provides an upper threshold that the PEC uses to remove the noise during strong zero crossing detection. Zero crossings are considered valid only if there is a sign change and id the difference between the 2nd derivative values of these two pixels is greater than the threshold.

PVP\_PEC\_D2TH1: PEC Strong Zero Crossing Threshold - R/W

Reset = 0x0000 0000

Figure 30-81: PVP\_PEC\_D2TH1 Register Diagram

Table 30-47: PVP\_PEC\_D2TH1 Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 14:0    | VALUE    | Strong Zero Crossing Threshold. |

IIMn Configuration

The integral image computation (IIM) block computes the rectangular integral image algorithm. The PVP\_IIMn\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_IIMn\_CFG: IIMn Configuration - R/W

Reset = 0x0000 0000

Figure 30-82: PVP\_IIMn\_CFG Register Diagram

**Table 30-48:** PVP\_IIMn\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## IIMn Scaling Values

The PVP\_IIMn\_SCALE holds the independently controlled scaling factors in each dimension for the output's programmable downscaler.

### PVP\_IIMn\_SCALE: IIMn Scaling Values - R/W

Reset = 0x0000 0000

**Figure 30-84:** PVP\_IIMn\_SCALE Register Diagram

IIMn Signed Overflow Status

The PVP\_IIMn\_SOVF\_STAT holds the signed overflow status, which is determined considering addition of 32-bit signed numbers.

PVP\_IIMn\_SOVF\_STAT: IIMn Signed Overflow Status - R/NW

Reset = 0x03ff 07ff

Figure 30-85: PVP\_IIMn\_SOVF\_STAT Register Diagram

# ACU Configuration

The arithmetic computation unit (ACU) block provides basic 32-bit math such as addition, subtraction, multiplication, and division. This block also features a 48-bit accumulator and can normalize and saturate on the output. The PVP\_ACU\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_ACU\_CFG: ACU Configuration - R/W

Reset = 0x0000 0000

Figure 30-87: PVP\_ACU\_CFG Register Diagram

Table 30-53: PVP\_ACU\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                   |

ACU Control

The PVP\_ACU\_CTL register selects operation modes for the arithmetic computation unit (ACU), including modes for sum, product, accumulate, and shift operations.

Figure 30-88: PVP\_ACU\_CTL Register Diagram

**Table 30-54:** PVP\_ACU\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                      |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 28      | SUMOP    | Sum Operation.<br>The PVP_ACU_CTL.SUMOP selects add or subtract as the SUM function.                                                         |
|         |          | 0 Add                                                                                                                                        |
|         |          | 1 Subtract                                                                                                                                   |
| 27      | SUMISW   | Sum Input Swap.<br>The PVP_ACU_CTL.SUMISW selects swapping of operands for the SUM function. The swap is meaningful for subtract operations. |
|         |          | 0 Do Not Swap Operands                                                                                                                       |
|         |          | 1 Swap Operands                                                                                                                              |
| 25:24   | SUMINP   | Sum Inputs for Adder.<br>The PVP_ACU_CTL.SUMINP selects the inputs to the adder for the SUM function.                                        |
|         |          | 0 X,Y Inputs                                                                                                                                 |
|         |          | 1 X,OFFSET Inputs                                                                                                                            |
|         |          | 2 Y,OFFSET Inputs                                                                                                                            |
|         |          | 3 Reserved                                                                                                                                   |
| 21:20   | PRDOP    | Prod Operation.<br>The PVP_ACU_CTL.PRDOP selects multiply or divide as the PROD operation.                                                   |
|         |          | 0 Multiply                                                                                                                                   |
|         |          | 1 Divide with Quotient                                                                                                                       |
|         |          | 2 Divide with Modulus                                                                                                                        |
|         |          | 3 Reserved                                                                                                                                   |

**Table 30-54:** PVP\_ACU\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 19      | PRDISW   | Prod Input Swap.<br>The PVP_ACU_CTL.PRDISW selects swapping of operands for the PROD function. The swap is meaningful for division operations. |
|         |          | 0 Do Not Swap Operands                                                                                                                         |
|         |          | 1 Swap Operands                                                                                                                                |
| 17:16   | PRDINP   | Prod Inputs for Mult/Div.<br>The PVP_ACU_CTL.PRDINP selects the inputs to the multiplier/divider for the PROD function.                        |
|         |          | 0 X,Y Inputs                                                                                                                                   |
|         |          | 1 X,FACTOR Inputs                                                                                                                              |
|         |          | 2 Y,FACTOR Inputs                                                                                                                              |
|         |          | 3 SUM,FACTOR Inputs                                                                                                                            |
| 15      | ACCFRAME | Accumulator Frame.<br>The PVP_ACU_CTL.ACCFRAME selects whether or not the accumulator is output and cleared after each row or frame.           |
|         |          | 0 Clear ACC After Row                                                                                                                          |
|         |          | 1 Clear ACC After Frame                                                                                                                        |
| 9:8     | ACCINP   | Accumulator Input.<br>The PVP_ACU_CTL.ACCINP selects the input to the accumulator for accumulate operations.                                   |
|         |          | 0 X Input                                                                                                                                      |
|         |          | 1 SUM Input                                                                                                                                    |
|         |          | 2 PROD Input                                                                                                                                   |
|         |          | 3 Reserved                                                                                                                                     |

**Table 30-54:** PVP\_ACU\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------|
| 1:0     | SFTINP   | Shift Input.<br>The PVP_ACU_CTL.SFTINP selects the input to the shifter for shift operations. |
|         |          | 0 X Input                                                                                     |
|         |          | 1 SUM Result Input                                                                            |
|         |          | 2 PROD Result Input                                                                           |
|         |          | 3 ACC Result Input                                                                            |

## ACU SUM Constant

The PVP\_ACU\_OFFSET provides the constant value (offset) input for the ACU SUM operation when the PVP\_ACU\_CTL.SUMINP field selects the offset as one of the inputs for the operation.

**PVP\_ACU\_OFFSET: ACU SUM Constant - R/W**

Reset = 0x0000 0000

**Figure 30-89:** PVP\_ACU\_OFFSET Register Diagram

**Table 30-55:** PVP\_ACU\_OFFSET Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | SUM Constant.           |

## ACU PROD Constant

The PVP\_ACU\_FACTOR provides the constant value (factor) input for the ACU PROD operation when the PVP\_ACU\_CTL.PR DINP field selects the factor as one of the inputs for the operation.

PVP\_ACU\_FACTOR: ACU PROD Constant - R/W

Reset = 0x0000 0000

Figure 30-90: PVP\_ACU\_FACTOR Register Diagram

Table 30-56: PVP\_ACU\_FACTOR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | PROD Constant.          |

ACU Shift Constant

The PVP\_ACU\_SHIFT provides the shift constant value (arithmetic right shift size in bits) for ACC SUM or PROD operations or for 48-bit output from the accumulator. The shift size is from 0 to 31 bits and can be bypassed by programming a value of 0 for the shift constant.

PVP\_ACU\_SHIFT: ACU Shift Constant - R/W

Reset = 0x0000 0000

Figure 30-91: PVP\_ACU\_SHIFT Register Diagram

Table 30-57: PVP\_ACU\_SHIFT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 5:0     | VALUE    | SHIFT Constant.         |

# ACU Lower Sat Threshold Min

The PVP\_ACU\_MIN holds the lower threshold value for saturation of ACU shifter output.

**PVP\_ACU\_MIN: ACU Lower Sat Threshold Min - R/W**

Reset = 0x8000 0000

**Figure 30-92:** PVP\_ACU\_MIN Register Diagram

**Table 30-58:** PVP\_ACU\_MIN Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 31:0    | VALUE    | Lower saturation threshold set to MIN. |

# ACU Upper Sat Threshold Max

The PVP\_ACU\_MAX holds the upper threshold value for saturation of ACU shifter output.

**PVP\_ACU\_MAX: ACU Upper Sat Threshold Max - R/W**

Reset = 0x7fff ffff

**Figure 30-93:** PVP\_ACU\_MAX Register Diagram

Table 30-59: PVP\_ACU\_MAX Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 31:0    | VALUE    | Upper saturation threshold set to MAX. |

UDS Configuration

The up-down scaler (UDS) block provides image resizing. The PVP\_UDS\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_UDS\_CFG: UDS Configuration - R/W

Reset = 0x0000 0004

Figure 30-94: PVP\_UDS\_CFG Register Diagram

Table 30-60: PVP\_UDS\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | IBLOCK0  | Input Block ID.<br>The blocks comprising the PVP pipe may connect to one or more output ports. The PVP_UDS_CFG.IBLOCK0 and PVP_UDS_CFG.IPORT0 fields determine which output port(s) are connected to the input port(s).                                                                                                              |
|         |          | 14 IPF1                                                                                                                                                                                                                                                                                                                              |
| 5:4     | IPORT0   | Input Port ID.<br>The blocks comprising the PVP pipe may connect to one or more output ports. The PVP_UDS_CFG.IBLOCK0 and PVP_UDS_CFG.IPORT0 fields determine which output port(s) are connected to the input port(s). For more information, see the connectivity tables for each input block in the architectural concepts section. |

**Table 30-60:** PVP\_UDS\_CFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                      |
|---------|----------|----------------------------------------------------------------------------------------------|
| 2       | MPIPE    | Memory Pipe.<br>The PVP_UDS_CFG.MPIPE bit always reads as 1 (memory pipe).                   |
| 0       | START    | Start.<br>The PVP_UDS_CFG.START enables the PVP. This bit reads 0 after the pipe is drained. |
|         |          | 1      Enable (W1A)                                                                          |

## UDS Control

The PVP\_UDS\_CTL register selects operation modes for the up-down scaler (UDS) block, including filter tap selection.

**PVP\_UDS\_CTL: UDS Control - R/W**

Reset = 0x0000 0000

**Figure 30-95:** PVP\_UDS\_CTL Register Diagram

**Table 30-61:** PVP\_UDS\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                     |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------|
| 0       | AAVG     | Automatic Averaging.<br>The PVP_UDS_CTL.AAVG selects automatic or manual filter tap selection for the anti-aliasing filter. |
|         |          | 0      Manual Filter Tap Selection                                                                                          |
|         |          | 1      Auto Filter Tap Selection                                                                                            |

## UDS Output HCNT

The PVP\_UDS\_OHCNT selects the horizontal dimension for the output frame. Legal values for the target frame are: 16, 32, 64, 80, 96, 112, and 128.

PVP\_UDS\_OHCNT: UDS Output HCNT - R/W

Reset = 0x0000 0000

Figure 30-96: PVP\_UDS\_OHCNT Register Diagram

Table 30-62: PVP\_UDS\_OHCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration      |
|---------|----------|------------------------------|
| 7:4     | VALUE    | H Dimension of Output Frame. |

## UDS Output VCNT

The PVP\_UDS\_OVCNT selects the vertical dimension for the output frame. Legal values for the target frame are: 16, 32, 64, 80, 96, 112, and 128.

PVP\_UDS\_OVCNT: UDS Output VCNT - R/W

Reset = 0x0000 0000

**Table 30-63:** PVP\_UDS\_OVCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration      |
|---------|----------|------------------------------|
| 7:4     | VALUE    | V Dimension of Output Frame. |

UDS HAVG

The PVP\_UDS\_HAVG selects the UDS H taps. Legal values for PVP\_UDS\_HAVG are between 1 and 128.

PVP\_UDS\_HAVG: UDS HAVG - R/W

Reset = 0x0000 0000

**Figure 30-98:** PVP\_UDS\_HAVG Register Diagram

**Table 30-64:** PVP\_UDS\_HAVG Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | H Filter Taps.          |

UDS VAVG

The PVP\_UDS\_VAVG selects the UDS V taps. Legal values for PVP\_UDS\_VAVG are between 1 and 64.

PVP\_UDS\_VAVG: UDS VAVG - R/W

Reset = 0x0000 0000

Figure 30-99: PVP\_UDS\_VAVG Register Diagram

Table 30-65: PVP\_UDS\_VAVG Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 6:0     | VALUE    | V Filter Taps.          |

IPF0 (Camera Pipe) Configuration

The input data formatter (IPF) blocks house FIFOs that buffer data for a sustained peak bandwidth output. The PVP\_IPF0\_CFG register enables the block's FIFO and configures blocks' connections within thePVP.

PVP\_IPF0\_CFG: IPF0 (Camera Pipe) Configuration - R/W

Reset = 0x0000 0000

Figure 30-100: PVP\_IPF0\_CFG Register Diagram

**Table 30-66:** PVP\_IPF0\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24   | STATWCNT | Camera Pipe DMA Status.<br>The PVP_IPF0_CFG.STATWCNT selects whether or not tag status is output on camera pipe status DMA channel. Note that all other values are reserved. |
|         |          | 0                      No Status Output                                                                                                                                      |
|         |          | 1                      Tag Status Output                                                                                                                                     |
| 2       | MPIPE    | Memory Pipe.<br>The PVP_IPF0_CFG.MPIPE bit always reads as 0 (camera pipe).                                                                                                  |
| 0       | START    | Start.<br>The PVP_IPF0_CFG.START enables the PVP. This bit reads 0 after the pipe is drained.                                                                                |
|         |          | 1                      Enable (W1A)                                                                                                                                          |

## IPFn (Camera/Memory Pipe) Pipe Control

The PVP\_IPFn\_PIPECTL register controls the IPFn block's pipeline features, including status transmission and drain operation.

**PVP\_IPFn\_PIPECTL: IPFn (Camera/Memory Pipe) Pipe Control - R/W**

Reset = 0x0000 0000

**Figure 30-101:** PVP\_IPFn\_PIPECTL Register Diagram

Table 30-67: PVP\_IPFn\_PIPECTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | STATEN   | DMA Status Enable.<br>The PVP_IPFn_PIPECTL.STATEN enables the IPF to send status DMA when PVP_IPFn_FCNT expires or every frame where PVP_IPFn_FCNT equals zero. |
|         |          | 0                      Disable                                                                                                                                  |
|         |          | 1                      Enable                                                                                                                                   |
| 0       | DRAIN    | Drain Enable.<br>The PVP_IPFn_PIPECTL.DRAIN enables the IPF to flush frames automatically in conjunction with PVP_IPFn_FCNT.                                    |
|         |          | 0                      Disable                                                                                                                                  |
|         |          | 1                      Enable                                                                                                                                   |

IPFn (Camera/Memory Pipe) Control

The PVP\_IPFn\_CTL register controls the IPFn block's pipeline features, including color format, format conversion, and output port selection.

PVP\_IPFn\_CTL: IPFn (Camera/Memory Pipe) Control - R/W

Reset = 0x0000 0000

Figure 30-102: PVP\_IPFn\_CTL Register Diagram

**Table 30-68:** PVP\_IPFn\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                      |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 27      | QFRMT    | Q Format Correction.<br>The PVP_IPFn_CTL.QFRMT enables Q format correction, converting data to unsigned by 1 left shift.                     |
|         |          | 0      Disable Q Format Correction                                                                                                           |
|         |          | 1      Enable Q Format Correction                                                                                                            |
| 26      | SIGNEXT  | Sign Extend.<br>The PVP_IPFn_CTL.SIGNEXT selects sign or zero extension for the extracted 5-, 6-, 8-, 16-, or 24-bit value to 32-bit value.  |
|         |          | 0      Zero Extend                                                                                                                           |
|         |          | 1      Sign Extend                                                                                                                           |
| 25      | EXTRED   | Extract Red/Green.<br>The PVP_IPFn_CTL.EXTRED selects red or green extraction from RGB format. This selection does not apply for YUV format. |
|         |          | 0      Extract Green                                                                                                                         |
|         |          | 1      Extract Red                                                                                                                           |
| 24      | UNPACK   | Unpack Incoming.<br>The PVP_IPFn_CTL.UNPACK enables unpacking for incoming data.                                                             |
|         |          | 0      No Unpacking                                                                                                                          |
|         |          | 1      Unpack Data                                                                                                                           |

**Table 30-68:** PVP\_IPFn\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 20:16   | CFRMT    | Color Space Format.<br>The PVP_IPFn_CTL.CFRMT field selects the Color Space Format. Note that all values other than those listed are reserved. |
|         |          | 0 RGB 8-Bit                                                                                                                                    |
|         |          | 1 RGB 888                                                                                                                                      |
|         |          | 2 RGB 565                                                                                                                                      |
|         |          | 3 RGB 666                                                                                                                                      |

## IPFn (Camera/Memory Pipe) TAG Value

The PVP\_IPFn\_TAG holds a unique, user-programmable tag value that indicates to which frame the values were applied. If there are situations where the software does not need information about whether or not a new control word was applied for a new frame, the tag need not be programmed.

PVP\_IPFn\_TAG: IPFn (Camera/Memory Pipe) TAG Value - R/W

Reset = 0x0000 0000

Figure 30-103: PVP\_IPFn\_TAG Register Diagram

Table 30-69: PVP\_IPFn\_TAG Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | TAG Value.              |

IPFn (Camera/Memory Pipe) Frame Count

The PVP\_IPFn\_FCNT whether a given block control structure list (BCL) applies to a set of frames or applies for every new frame.

PVP\_IPFn\_FCNT: IPFn (Camera/Memory Pipe) Frame Count - R/W

Reset = 0x0000 0000

Figure 30-104: PVP\_IPFn\_FCNT Register Diagram

Table 30-70: PVP\_IPFn\_FCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Frame or ROI Count.     |

IPFn (Camera/Memory Pipe) Horizontal Count

The PVP\_IPFn\_HCNT contains the horizontal count (in pixels) for the region of interest (ROI) starting at the PVP\_IPF0\_HPOS position.

PVP\_IPFn\_HCNT: IPFn (Camera/Memory Pipe) Horizontal Count - R/W

Reset = 0x0000 0000

Figure 30-105: PVP\_IPFn\_HCNT Register Diagram

Table 30-71: PVP\_IPFn\_HCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | Effective Width of ROI. |

IPFn (Camera/Memory Pipe) Vertical Count

The PVP\_IPFn\_VCNT contains the vertical count (in pixels) for the region of interest (ROI) starting at the PVP\_IPF0\_VPOS position.

PVP\_IPFn\_VCNT: IPFn (Camera/Memory Pipe) Vertical Count - R/W

Reset = 0x0000 0000

Figure 30-106: PVP\_IPFn\_VCNT Register Diagram

Table 30-72: PVP\_IPFn\_VCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 15:0    | VALUE    | Effective Height of ROI. |

IPF0 (Camera Pipe) Horizontal Position

The PVP\_IPF0\_HPOS contains the horizontal starting position (in pixels) for the region of interest (ROI).

PVP\_IPF0\_HPOS: IPF0 (Camera Pipe) Horizontal Position - R/W

Reset = 0x0000 0000

Figure 30-107: PVP\_IPF0\_HPOS Register Diagram

Table 30-73: PVP\_IPF0\_HPOS Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 15:0    | VALUE    | Horizontal Delay of ROI. |

IPF0 (Camera Pipe) Vertical Position

The PVP\_IPF0\_VPOS contains the vertical starting position (in pixels) for the region of interest (ROI).

**PVP\_IPF0\_VPOS: IPF0 (Camera Pipe) Vertical Position - R/W**

Reset = 0x0000 0000

**Figure 30-108:** PVP\_IPF0\_VPOS Register Diagram

**Table 30-74:** PVP\_IPF0\_VPOS Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | Vertical Delay of ROI.  |

**IPF<sub>n</sub> (Camera/Memory Pipe) TAG Status**

After daisy chain load is completed, the value in PVP\_IPF<sub>n</sub>\_TAG is loaded to the PVP\_IPF<sub>n</sub>\_TAG\_STAT. This register is read-only register and may also be read through status read DMA. The PVP\_IPF<sub>n</sub>\_TAG\_STAT register is double buffered internally with the PVP\_IPF<sub>n</sub>\_TAG\_STAT corresponding to previous PVP\_IPF<sub>n</sub>\_FCNT entity is sent on status DMA.

**PVP\_IPF<sub>n</sub>\_TAG\_STAT: IPF<sub>n</sub> (Camera/Memory Pipe) TAG Status - R/NW**

Reset = 0x0000 0000

**Figure 30-109:** PVP\_IPF<sub>n</sub>\_TAG\_STAT Register Diagram

**Table 30-75:** PVP\_IPF<sub>n</sub>\_TAG\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | TAG Value.              |

IPF1 (Memory Pipe) Configuration

The PVP\_IPF1\_CFG register controls the IPF1 block's pipeline features, including status transmission and drain operation.

PVP\_IPF1\_CFG: IPF1 (Memory Pipe) Configuration - R/W

Reset = 0x0000 0004

Figure 30-110: PVP\_IPF1\_CFG Register Diagram

Table 30-76: PVP\_IPF1\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                             |                   |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 31:24   | STATWCNT | Status Word Count.<br>The PVP_IPF1_CFG.STATWCNT select the camera pipe DMA status information to be output on the memory pipe DMA channel. Note that all other values are reserved. |                   |
|         |          | 0                                                                                                                                                                                   | No Status Output  |
|         |          | 1                                                                                                                                                                                   | Tag Status Output |

Table 30-77: PVP\_CNVn\_CFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:4     | IPORT0   | Input Port ID.<br>The blocks comprising the PVP pipe may connect to one or more output ports. The PVP_CNVn_CFG.IBLOCK0 and PVP_CNVn_CFG.IPORT0 fields determine which output port(s) are connected to the input port(s). For more information, see the connectivity tables for each input block in the architectural concepts section. |
| 2       | MPIPE    | Memory Pipe.<br>The PVP_CNVn_CFG.MPIPE bit selects memory pipe or camera pipe.                                                                                                                                                                                                                                                         |
|         |          | 0      Camera Pipe                                                                                                                                                                                                                                                                                                                     |
|         |          | 1      Memory Pipe                                                                                                                                                                                                                                                                                                                     |
| 0       | START    | Start.<br>The PVP_CNVn_CFG.START enables the PVP. This bit reads 0 after the pipe is drained.                                                                                                                                                                                                                                          |
|         |          | 1      Enable (W1A)                                                                                                                                                                                                                                                                                                                    |

CNVn Control

The PVP\_CNVn\_CTL register controls the CNVn block's convolution features, including output saturation, output right shift, and zero/data fill selection.

PVP\_CNVn\_CTL: CNVn Control - R/W

Reset = 0x0000 0000

Figure 30-112: PVP\_CNVn\_CTL Register Diagram

**Table 30-78:** PVP\_CNVn\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8:4     | SHIFT    | Shift Right.<br>The PVP_CNVn_CTL.SHIFT selects arithmetic right shift of output from 0 to 31 bits.                                                                                                                                                          |
| 1       | ZEROFILL | Zero Fill.<br>The PVP_CNVn_CTL.ZEROFILL select whether to fill edge data with zeroes or with duplicated pixels.                                                                                                                                             |
|         |          | 0 Duplicated Data Fill                                                                                                                                                                                                                                      |
|         |          | 1 Zero Fill                                                                                                                                                                                                                                                 |
| 0       | SAT32    | Saturate Output to 32 Bits.<br>The PVP_CNVn_CTL.SAT32 selects whether to saturate output to highest 32-bit value or highest 16-bit value. For 16-bit saturate of output, the value is driven on the lower 16 bits, and the upper 16 bits are sign-extended. |
|         |          | 0 16-Bit Saturate of Output                                                                                                                                                                                                                                 |
|         |          | 1 32-Bit Saturate of Output                                                                                                                                                                                                                                 |

## CNVn Coefficients 0,0 and 0,1

The PVP\_CNVn\_C00C01 provides coefficients 0,0 and 0,1 for the convolution matrix.

**PVP\_CNVn\_C00C01: CNVn Coefficients 0,0 and 0,1 - R/W**

Reset = 0x0000 0000

**Figure 30-113:** PVP\_CNVn\_C00C01 Register Diagram

Table 30-79: PVP\_CNVn\_C00C01 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C01      | Coefficient 0, 1.       |
| 15:0    | C00      | Coefficient 0, 0.       |

CNVn Coefficients 0,2 and 0,3

The PVP\_CNVn\_C02C03 provides coefficients 0,2 and 0,3 for the convolution matrix.

PVP\_CNVn\_C02C03: CNVn Coefficients 0,2 and 0,3 - R/W

Reset = 0x0000 0000

Figure 30-114: PVP\_CNVn\_C02C03 Register Diagram

Table 30-80: PVP\_CNVn\_C02C03 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C03      | Coefficient 0, 3.       |
| 15:0    | C02      | Coefficient 0, 2.       |

CNVn Coefficient 0,4

The PVP\_CNVn\_C04 provides coefficients 0,4 for the convolution matrix.

**PVP\_CNVn\_C04: CNVn Coefficient 0,4 - R/W**

Reset = 0x0000 0000

**Figure 30-115:** PVP\_CNVn\_C04 Register Diagram

**Table 30-81:** PVP\_CNVn\_C04 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C04      | Coefficient 0, 4.       |

## CNVn Coefficients 1,0 and 1,1

The PVP\_CNVn\_C10C11 provides coefficients 1,0 and 1,1 for the convolution matrix.

**PVP\_CNVn\_C10C11: CNVn Coefficients 1,0 and 1,1 - R/W**

Reset = 0x0000 0000

**Figure 30-116:** PVP\_CNVn\_C10C11 Register Diagram

**Table 30-82:** PVP\_CNVn\_C10C11 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C11      | Coefficient 1, 1.       |
| 15:0    | C10      | Coefficient 1, 0.       |

CNVn Coefficients 1,2 and 1,3

The PVP\_CNVn\_C12C13 provides coefficients 1,2 and 1,3 for the convolution matrix.

PVP\_CNVn\_C12C13: CNVn Coefficients 1,2 and 1,3 - R/W

Reset = 0x0000 0000

Figure 30-117: PVP\_CNVn\_C12C13 Register Diagram

Table 30-83: PVP\_CNVn\_C12C13 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C13      | Coefficient 1, 3.       |
| 15:0    | C12      | Coefficient 1, 2.       |

CNVn Coefficient 1,4

The PVP\_CNVn\_C14 provides coefficients 1,4 for the convolution matrix.

PVP\_CNVn\_C14: CNVn Coefficient 1,4 - R/W

Reset = 0x0000 0000

Figure 30-118: PVP\_CNVn\_C14 Register Diagram

**Table 30-84:** PVP\_CNVn\_C14 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C14      | Coefficient 1, 4.       |

CNVn Coefficients 2,0 and 2,1

The PVP\_CNVn\_C20C21 provides coefficients 2,0 and 2,1 for the convolution matrix.

PVP\_CNVn\_C20C21: CNVn Coefficients 2,0 and 2,1 - R/W

Reset = 0x0000 0000

**Figure 30-119:** PVP\_CNVn\_C20C21 Register Diagram

**Table 30-85:** PVP\_CNVn\_C20C21 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C21      | Coefficient 2, 1.       |
| 15:0    | C20      | Coefficient 2, 0.       |

CNVn Coefficients 2,2 and 2,3

The PVP\_CNVn\_C22C23 provides coefficients 2,2 and 2,3 for the convolution matrix.

PVP\_CNVn\_C22C23: CNVn Coefficients 2,2 and 2,3 - R/W

Reset = 0x0000 0000

Figure 30-120: PVP\_CNVn\_C22C23 Register Diagram

Table 30-86: PVP\_CNVn\_C22C23 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C23      | Coefficient 2, 3.       |
| 15:0    | C22      | Coefficient 2, 2.       |

CNVn Coefficient 2,4

The PVP\_CNVn\_C24 provides coefficients 2,4 for the convolution matrix.

PVP\_CNVn\_C24: CNVn Coefficient 2,4 - R/W

Reset = 0x0000 0000

Figure 30-121: PVP\_CNVn\_C24 Register Diagram

Table 30-87: PVP\_CNVn\_C24 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C24      | Coefficient 2, 4.       |

## CNVn Coefficients 3,0 and 3,1

The PVP\_CNVn\_C30C31 provides coefficients 3,0 and 3,1 for the convolution matrix.

**PVP\_CNVn\_C30C31: CNVn Coefficients 3,0 and 3,1 - R/W**

Reset = 0x0000 0000

**Figure 30-122:** PVP\_CNVn\_C30C31 Register Diagram

**Table 30-88:** PVP\_CNVn\_C30C31 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C31      | Coefficient 3, 1.       |
| 15:0    | C30      | Coefficient 3, 0.       |

## CNVn Coefficients 3,2 and 3,3

The PVP\_CNVn\_C32C33 provides coefficients 3,2 and 3,3 for the convolution matrix.

**PVP\_CNVn\_C32C33: CNVn Coefficients 3,2 and 3,3 - R/W**

Reset = 0x0000 0000

**Figure 30-123:** PVP\_CNVn\_C32C33 Register Diagram

Table 30-89: PVP\_CNVn\_C32C33 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C33      | Coefficient 3, 3.       |
| 15:0    | C32      | Coefficient 3, 2.       |

CNVn Coefficient 3,4

The PVP\_CNVn\_C34 provides coefficients 3,4 for the convolution matrix.

PVP\_CNVn\_C34: CNVn Coefficient 3,4 - R/W

Reset = 0x0000 0000

Figure 30-124: PVP\_CNVn\_C34 Register Diagram

Table 30-90: PVP\_CNVn\_C34 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C34      | Coefficient 3, 4.       |

CNVn Coefficients 4,0 and 4,1

The PVP\_CNVn\_C40C41 provides coefficients 4,0 and 4,1 for the convolution matrix.

**PVP\_CNVn\_C40C41: CNVn Coefficients 4,0 and 4,1 - R/W**

Reset = 0x0000 0000

**Figure 30-125:** PVP\_CNVn\_C40C41 Register Diagram

**Table 30-91:** PVP\_CNVn\_C40C41 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C41      | Coefficient 4, 1.       |
| 15:0    | C40      | Coefficient 4, 0.       |

## CNVn Coefficients 4,2 and 4,3

The PVP\_CNVn\_C42C43 provides coefficients 4,2 and 4,3 for the convolution matrix.

**PVP\_CNVn\_C42C43: CNVn Coefficients 4,2 and 4,3 - R/W**

Reset = 0x0000 0000

**Figure 30-126:** PVP\_CNVn\_C42C43 Register Diagram

**Table 30-92:** PVP\_CNVn\_C42C43 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | C43      | Coefficient 4, 3.       |
| 15:0    | C42      | Coefficient 4, 2.       |

Table 30-92: PVP\_CNVn\_C42C43 Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C42      | Coefficient 4, 2.       |

CNVn Coefficient 4,4

The PVP\_CNVn\_C44 provides coefficients 4,4 for the convolution matrix.

PVP\_CNVn\_C44: CNVn Coefficient 4,4 - R/W

Reset = 0x0000 0000

Figure 30-127: PVP\_CNVn\_C44 Register Diagram

Table 30-93: PVP\_CNVn\_C44 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | C44      | Coefficient 4, 4.       |

CNVn Scaling Factor

The PVP\_CNVn\_SCALE holds the vertical and horizontal scaling factors for down scaling incoming frames with decimation ratios of up to 256 (for example, 1, 2, 4, 8, 16, 32, 64, 128, or 256) in either direction.

**PVP\_CNvN\_SCALE: CNvN Scaling Factor - R/W**

Reset = 0x0000 0000

**Figure 30-128:** PVP\_CNvN\_SCALE Register Diagram

**Table 30-94:** PVP\_CNvN\_SCALE Register Fields

| Bit No. | Bit Name | Description/Enumeration    |
|---------|----------|----------------------------|
| 24:16   | VSCL     | Vertical Scaling factor.   |
| 9:0     | HSCL     | Horizontal Scaling factor. |

**THCn Configuration**

The PVP\_THCn\_CFG register controls the threshold/histogram and compression engine (THC) block's pipeline features, including status transmission, port selection, and block enable.

**PVP\_THCn\_CFG: THCn Configuration - R/W**

Reset = 0x0000 0000

**Figure 30-129:** PVP\_THCn\_CFG Register Diagram

**Table 30-95:** PVP\_THCn\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24   | STATWCNT | Status Word Count.<br>The PVP_THCn_CFG.STATWCNT select the camera pipe status information to be output on the memory pipe DMA channel. Note that all other values are reserved.                                                                                                                                                        |
| 15:8    | IBLOCK0  | Input Block ID.<br>The blocks comprising the PVP pipe may connect to one or more output ports. The PVP_THCn_CFG.IBLOCK0 and PVP_THCn_CFG.IPORT0 fields determine which output port(s) are connected to the input port(s).                                                                                                              |

| 5:4     | IPORT0   | Input Port ID.<br>The blocks comprising the PVP pipe may connect to one or more output ports. The PVP_THCn_CFG.IBLOCK0 and PVP_THCn_CFG.IPORT0 fields determine which output port(s) are connected to the input port(s). For more information, see the connectivity tables for each input block in the architectural concepts section. |

**Table 30-95:** PVP\_THCn\_CFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------|
| 2       | MPIPE    | Memory Pipe.<br>The PVP_THCn_CFG.MPIPE bit selects memory pipe or camera pipe.                |
|         |          | 0 Camera Pipe                                                                                 |
|         |          | 1 Memory Pipe                                                                                 |
| 0       | START    | Start.<br>The PVP_THCn_CFG.START enables the PVP. This bit reads 0 after the pipe is drained. |
|         |          | 1 Enable (W1A)                                                                                |

THCn Control

The PVP\_THCn\_CTL register controls the THCn block's threshold/histogram features, including histogram window and counters, output format, and threshold mode selection.

PVP\_THCn\_CTL: THCn Control - R/W

Reset = 0x0000 0000

| 8       | RLEFRAME | Run-Length-Encode Frame.<br>The PVP_THCn_CTL.RLEFRAME selects the scope for run-length compression as row or frame. When row is selected, the compression block generates a report at the end of a row and the run-length counter is reset. When frame is selected, compression works across rows in the frame. Note that, due to the nature of compression, a variable number of reports are generated per row or per frame. |
|         |          | 0      Row (Line) Compression                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1      Frame Compression                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 30-96:** PVP\_THCn\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                     |

|         |          | 2 Hysteresis Mode                                                                                                                                                                                |
|         |          | 3 Reserved                                                                                                                                                                                       |

THCn Histogram Frame Count

The PVP\_THCn\_HFCNT holds the number of frames for which the histogram counters accumulate. The PVP\_THCn\_HFCNT\_STAT register counts frames up to the value set in PVP\_THCn\_HFCNT for histogram operation.

PVP\_THCn\_HFCNT: THCn Histogram Frame Count - R/W

Reset = 0x0000 0001

Figure 30-131: PVP\_THCn\_HFCNT Register Diagram

Table 30-97: PVP\_THCn\_HFCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | THCn HFCNT Value.       |

# THCn Max RLE Reports

This PVP\_THCn\_RMAXREP controls the maximum number of RLE reports per line or per frame.

PVP\_THCn\_RMAXREP: THCn Max RLE Reports - R/W

Reset = 0x0000 0020

Figure 30-132: PVP\_THCn\_RMAXREP Register Diagram

Table 30-98: PVP\_THCn\_RMAXREP Register Fields

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 31:0    | VALUE    | THCn Max RLE Reports Value. |

# THCn Min Clip Value

The PVP\_THCn\_CMINVAL holds the minimum clip value, which the THC uses in clipping/saturation mode. For more information about this mode and the registers involved in its operation (PVP\_THCn\_CMINVAL, PVP\_THCn\_CMINTH, PVP\_THCn\_CMAXTH,PVP\_THCn\_CMAXVAL), see the PVP functional description.

PVP\_THCn\_CMINVAL: THCn Min Clip Value - R/W

Reset = 0x8000 0000

Figure 30-133: PVP\_THCn\_CMINVAL Register Diagram

Table 30-99: PVP\_THCn\_CMINVAL Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Clip Min Value.         |

THCn Clip Min Threshold

The PVP\_THCn\_CMINTH holds the minimum clip value, which the THC uses in clipping/saturation mode. For more information about this mode and the registers involved in its operation (PVP\_THCn\_CMINVAL, PVP\_THCn\_CMINTH, PVP\_THCn\_CMAXTH,PVP\_THCn\_CMAXVAL), see the PVP functional description.

PVP\_THCn\_CMINTH: THCn Clip Min Threshold - R/W

Reset = 0x8000 0000

Figure 30-134: PVP\_THCn\_CMINTH Register Diagram

Table 30-100: PVP\_THCn\_CMINTH Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Clip Min Threshold.     |

THCn Clip Max Threshold

The PVP\_THCn\_CMAXTH holds the minimum clip value, which the THC uses in clipping/saturation mode. For more information about this mode and the registers involved in its operation (PVP\_THCn\_CMINVAL, PVP\_THCn\_CMINTH, PVP\_THCn\_CMAXTH,PVP\_THCn\_CMAXVAL), see the PVP functional description.

**PVP\_THCn\_CMAXTH: THCn Clip Max Threshold - R/W**

Reset = 0x7fff ffff

**Figure 30-135:** PVP\_THCn\_CMAXTH Register Diagram

**Table 30-101:** PVP\_THCn\_CMAXTH Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Clip Max Threshold.     |

**THCn Max Clip Value**

The PVP\_THCn\_CMAXVAL holds the minimum clip value, which the THC uses in clipping/saturation mode. For more information about this mode and the registers involved in its operation (PVP\_THCn\_CMINVAL, PVP\_THCn\_CMINTH, PVP\_THCn\_CMAXTH,PVP\_THCn\_CMAXVAL), see the PVP functional description.

**PVP\_THCn\_CMAXVAL: THCn Max Clip Value - R/W**

Reset = 0x7fff ffff

**Figure 30-136:** PVP\_THCn\_CMAXVAL Register Diagram

**Table 30-102:** PVP\_THCn\_CMAXVAL Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Clip Max Value.         |

THCn Threshold Value 0

The PVP\_THCn\_TH0 holds one of up to 16 threshold values, which the THC uses in quantization mode and hysteresis mode. For more information about these modes and the registers involved in their operation, see the PVP functional description.

PVP\_THCn\_TH0: THCn Threshold Value 0 - R/W

Reset = 0x7fff ffff

Figure 30-137: PVP\_THCn\_TH0 Register Diagram

Table 30-103: PVP\_THCn\_TH0 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Threshold Value.        |

THCn Threshold Value 1

The PVP\_THCn\_TH1 holds one of up to 16 threshold values, which the THC uses in quantization mode and hysteresis mode. For more information about these modes and the registers involved in their operation, see the PVP functional description.

PVP\_THCn\_TH1: THCn Threshold Value 1 - R/W

Reset = 0x7fff ffff

Figure 30-138: PVP\_THCn\_TH1 Register Diagram

**THCn RLE Horizontal Count**

The PVP\_THCn\_RHCNT provides RLE encoder window information that the PVP uses for RLE compression operations.

**PVP\_THCn\_RHCNT: THCn RLE Horizontal Count - R/W**

Reset = 0x0000 0000

**Figure 30-159:** PVP\_THCn\_RHCNT Register Diagram

Table 30-125: PVP\_THCn\_RHCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                            |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | RLE Encoder Window Horizontal Count.<br>The PVP_THCn_RHCNT.VALUE provides the RLE encoder window width (count) in the X dimension. |

THCn RLE Vertical Count

The PVP\_THCn\_RVCNT provides RLE encoder window information that the PVP uses for RLE compression operations.

PVP\_THCn\_RVCNT: THCn RLE Vertical Count - R/W

Reset = 0x0000 0000

Figure 30-160: PVP\_THCn\_RVCNT Register Diagram

Table 30-126: PVP\_THCn\_RVCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                            |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | RLE Encoder Window Horizontal Count.<br>The PVP_THCn_RVCNT.VALUE provides the RLE encoder window width (count) in the Y dimension. |

THCn Histogram Frame Count Status

The PVP\_THCn\_HFCNT\_STAT indicates the current histogram frame count. The number of frames for which the histogram counters operate is determined by the PVP\_THCn\_HFCNT register. On reaching this count, the histogram counters are cleared and restart again.

**PVP\_THCn\_HFCNT\_STAT: THCn Histogram Frame Count Status - R/NW**

Reset = 0x0000 0000

**Figure 30-161:** PVP\_THCn\_HFCNT\_STAT Register Diagram

**Table 30-127:** PVP\_THCn\_HFCNT\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration          |
|---------|----------|----------------------------------|
| 31:0    | VALUE    | Current Histogram Frame Counter. |

## THCn Histogram Counter Value 0

The PVP\_THCn\_HCNT0\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

**PVP\_THCn\_HCNT0\_STAT: THCn Histogram Counter Value 0 - R/NW**

Reset = 0x0000 0000

**Figure 30-162:** PVP\_THCn\_HCNT0\_STAT Register Diagram

**Table 30-128:** PVP\_THCn\_HCNT0\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Histogram Counter Value 1

The PVP\_THCn\_HCNT1\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT1\_STAT: THCn Histogram Counter Value 1 - R/NW

Reset = 0x0000 0000

Figure 30-163: PVP\_THCn\_HCNT1\_STAT Register Diagram

Table 30-129: PVP\_THCn\_HCNT1\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Histogram Counter Value 2

The PVP\_THCn\_HCNT2\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT2\_STAT: THCn Histogram Counter Value 2 - R/NW

Reset = 0x0000 0000

Figure 30-164: PVP\_THCn\_HCNT2\_STAT Register Diagram

**Table 30-130:** PVP\_THCn\_HCNT2\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 3

The PVP\_THCn\_HCNT3\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

**PVP\_THCn\_HCNT3\_STAT: THCn Histogram Counter Value 3 - R/NW**

Reset = 0x0000 0000

**Figure 30-165:** PVP\_THCn\_HCNT3\_STAT Register Diagram

**Table 30-131:** PVP\_THCn\_HCNT3\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 4

The PVP\_THCn\_HCNT4\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT4\_STAT: THCn Histogram Counter Value 4 - R/NW

Reset = 0x0000 0000

Figure 30-166: PVP\_THCn\_HCNT4\_STAT Register Diagram

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

THCn Histogram Counter Value 5

The PVP\_THCn\_HCNT5\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT5\_STAT: THCn Histogram Counter Value 5 - R/NW

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 6

The PVP\_THCn\_HCNT6\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT6\_STAT: THCn Histogram Counter Value 6 - R/NW

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 7

The PVP\_THCn\_HCNT7\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT7\_STAT: THCn Histogram Counter Value 7 - R/NW

Reset = 0x0000 0000

Figure 30-169: PVP\_THCn\_HCNT7\_STAT Register Diagram

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

THCn Histogram Counter Value 8

The PVP\_THCn\_HCNT8\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT8\_STAT: THCn Histogram Counter Value 8 - R/NW

Reset = 0x0000 0000

Figure 30-170: PVP\_THCn\_HCNT8\_STAT Register Diagram

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

THCn Histogram Counter Value 9

The PVP\_THCn\_HCNT9\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

**PVP\_THCn\_HCNT9\_STAT: THCn Histogram Counter Value 9 - R/NW**

Reset = 0x0000 0000

**Figure 30-171:** PVP\_THCn\_HCNT9\_STAT Register Diagram

**Table 30-137:** PVP\_THCn\_HCNT9\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Histogram Counter Value 10

The PVP\_THCn\_HCNT10\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

**PVP\_THCn\_HCNT10\_STAT: THCn Histogram Counter Value 10 - R/NW**

Reset = 0x0000 0000

**Figure 30-172:** PVP\_THCn\_HCNT10\_STAT Register Diagram

**Table 30-138:** PVP\_THCn\_HCNT10\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Histogram Counter Value 11

The PVP\_THCn\_HCNT11\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT11\_STAT: THCn Histogram Counter Value 11 - R/NW

Reset = 0x0000 0000

Figure 30-173: PVP\_THCn\_HCNT11\_STAT Register Diagram

Table 30-139: PVP\_THCn\_HCNT11\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Histogram Counter Value 12

The PVP\_THCn\_HCNT12\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT12\_STAT: THCn Histogram Counter Value 12 - R/NW

Reset = 0x0000 0000

Figure 30-174: PVP\_THCn\_HCNT12\_STAT Register Diagram

**Table 30-140:** PVP\_THCn\_HCNT12\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 13

The PVP\_THCn\_HCNT13\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

**PVP\_THCn\_HCNT13\_STAT: THCn Histogram Counter Value 13 - R/NW**

Reset = 0x0000 0000

**Figure 30-175:** PVP\_THCn\_HCNT13\_STAT Register Diagram

**Table 30-141:** PVP\_THCn\_HCNT13\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

### THCn Histogram Counter Value 14

The PVP\_THCn\_HCNT14\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT14\_STAT: THCn Histogram Counter Value 14 - R/NW

Reset = 0x0000 0000

Figure 30-176: PVP\_THCn\_HCNT14\_STAT Register Diagram

Table 30-142: PVP\_THCn\_HCNT14\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

THCn Histogram Counter Value 15

The PVP\_THCn\_HCNT15\_STAT holds the current value for one of the histogram counters. If a histogram counter reaches the maximum value (0xFFFFFFFF) before expiry of histogram frame count (PVP\_THCn\_HFCNT), the histogram counters do not overflow, but saturate at that value.

PVP\_THCn\_HCNT15\_STAT: THCn Histogram Counter Value 15 - R/NW

Reset = 0x0000 0000

Figure 30-177: PVP\_THCn\_HCNT15\_STAT Register Diagram

Table 30-143: PVP\_THCn\_HCNT15\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Histogram counter value. |

## THCn Number of RLE Reports

The PVP\_THCn\_RREP\_STAT holds the number of RLE reports. The PVP generates the run length reports at the output of the module as soon as they are available. Note that there is a variable number of reports generated per line or per frame, depending on the pixel patterns.

PVP\_THCn\_RREP\_STAT: THCn Number of RLE Reports - R/NW

Reset = 0x0000 0000

Figure 30-178: PVP\_THCn\_RREP\_STAT Register Diagram

Table 30-144: PVP\_THCn\_RREP\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Number of RLE Reports.  |

## PMA Configuration

The PVP\_PMA\_CFG register controls the pixel magnitude and angle computation unit (PMA) block's pipeline features, including port selection and block enable.

**PVP\_PMA\_CFG: PMA Configuration - R/W**

Reset = 0x0000 0000

**Figure 30-179:** PVP\_PMA\_CFG Register Diagram

**Table 30-145:** PVP\_PMA\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                   |

# 31 Enhanced Parallel Peripheral Interface (EPPI)

The enhanced parallel peripheral interface (EPPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCD, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each EPPI has a DMA channel associated with it. Moreover, in some modes, a EPPI may use an additional DMA channel.

## EPPI Features

The following features are supported in the EPPI module.

- Programmable data length: 8, 10, 12, 14, 16, 18 and 24 bits per clock cycle
- Bidirectional and half-duplex port
- Internal or external clock source
- Clock gating by an external device asserting the clock gating control signal
- Various framed and non-framed operating modes as well as internal or external frame syncs
- Various general-purpose modes with 1, 2, 3 and 0 frame sync modes for both receive and transmit
- Ignores premature external frame syncs for data consistency
- SMPTE274M and SMPTE 296M high definition format support
- ITU-656, SMPTE 296M and SMPTE 274M status word error detection and correction for ITU-656 receive modes (at sampling frequencies less than or equal to 74.25 MHz)
- ITU-656 receive modes – active video only, vertical blanking only, and entire field
- ITU-656, SMPTE 296M and SMPTE 274M preamble and status word decode (at sampling frequencies less than or equal to 74.25 MHz)
- Optional packing and unpacking of data to/from 32 bits from/to 8, 16 and 24 bits. If packing/unpacking is enabled, endianness can be altered to change the order of packing/unpacking of bytes/words
- Optional sign extension or zero-fill and alternate even or odd data sample filter for receive modes
- RGB888 to RGB666 or RGB565 conversion for transmit modes
- 4:2:2 YCrCb data Tx/Rx interleaving/de-interleaving modes

- Configurable LCD data enable (DEN) output available on frame sync 3
- Supports delayed start of PPI frame syncs
- Data clipping and mirroring
- Horizontal and vertical windowing for general-purpose 2 and 3 frame sync modes
- Preamble, blanking and stripping support
- Multiplexing dual input

## EPPI Functional Description

The following sections provide a functional descriptions of the EPPI.

### RGB Data Formats

For transmit modes, the EPPI can convert RGB888 data in memory to RGB666 at the output if the `RGBFMTEN` bit is set in the `EPPI_CTL` register and if `DLEN` is equal to 18 bits. Similarly, the EPPI can convert RGB888 data in memory to RGB565 at the output if the `RGBFMTEN` bit is set in the `EPPI_CTL` register and if `DLEN` is equal to 16 bits.

This conversion is done as follows: if `PACKEN` = 1, the EPPI first unpacks, according to the `SWAPEN` settings, the three 32-bit data words from the DMA into four 24-bit data words to be transmitted out as described earlier. If `PACKEN` = 0, then the EPPI takes the lower 24 bits of the 32-bit DMA as the data to be transmitted. Then the EPPI truncates this 24-bit data word to the required data width by removing the lower 2 bits of G and the lower 2 or 3 bits of R and B.

### Data Clipping

The EPPI contains two registers to define the lower and upper limits for the Luma and Chroma components. This is used for clipping data values during 8, 10, 12 or 16-bit transmit modes. All data values for odd samples which are less than the value in the `LOW_ODD` field in the `EPPI_ODDCLIP` register are replaced with the value in the `LOW_ODD` field and all data values for even samples which are less than the value in the `LOW_EVEN` field in the `EPPI_EVENCLIP` register are replaced with the value in the `LOW_EVEN` field.

In the same manner, all data values for odd samples which are more than the value in the `HIGH_ODD` field in the `EPPI_ODDCLIP` register are replaced with the value in the `HIGH_ODD` field and all data values for even samples which are more than the values in the `HIGH_EVEN` field are replaced with the values in the `HIGH_EVEN` field. Depending upon the programmed EPPI length, only the corresponding bits (least aligned) are considered for clipping. For example if the EPPI is programmed in 10-bit mode, bits 9–0 and bits 25–16 constitute the clipping thresholds. The higher bits are ignored. The EPPI supports 8, 10, 12, and 16-bit clipping thresholds.

For the 4:2:2 YCrCb color space, Luma and Chroma typically have different lower and upper thresholds, which is why separate thresholds may be required for even and odd data samples. In the case of mono-chrome (Y only) or some non-video clipping applications, the value in the LOW\_ODD field should be the same as the value in the LOW\_EVEN field, and the value in the HIGH\_ODD field should be the same as the value in the HIGH\_EVEN field.

In GP 0 FS mode with internal blanking generation, clipping is valid only for the active video part of the transmitted data. ITU-R 656 preambles, status words and blanking data bypass the clipping logic.

If the EPPI is programmed in 16, 20 or 24-bit mode with SPLTWRD bit set, the YDATA (luma data) gets the clipping threshold levels of EPPI\_EVENCLIP and the CDATE (chroma data) gets the clipping threshold levels of EPPI\_ODDCLIP.

The clipping registers are ignored when the RGBFMTEN bit is set in the EPPI\_CTL register.

## Data Mirroring

To increase the pin multiplexing options with respect to the EPPI data pins, an additional data mirroring feature is available which mirrors the EPPI data bits 15–0. The MMR bit (DMRR) if set, mirrors the bits (default is DMRR = 0, no mirror). The complete description of this bit is provided in EPPI\_CTL register section. This feature is available in both transmit and receive.

**Figure 31-1:** Data Mirroring Receive

**Figure 31-2:** Data Mirroring Transmit

## Windowing

The EPPI supports windowing for GP input modes. The module can be configured to bring in a region of interest instead of the entire frame of data. This helps reduce bandwidth.

## Preamble, Blanking and Stripping Support

The module supports embedding blanking information and clipping active data to be transmitted. However this is limited to either single channel data or interleaved data (for example Y alone, C alone, or Y-Cr/Cb interleaved). Adding blanking information or clipping the data is not available for data sent in parallel [Y:Cr/Cb] for  $DLEN = 20$  or  $24$  bits, as would be the case with SMPTE modes. To support all the SMPTE modes, this logic is extended to  $20$  and  $24$  bits. The additional logic goes into the receive (preamble correction, sign extension) and transmit (blankgen and clipping) modes. This feature is available for  $DLEN = 16$  bits as well.

The EPPI supports preamble generation/detection and blank stripping for the two HD formats SMPTE 274M and 294M. The SMPTE standards are shown below in the table as a comparison with the ITU 656 modes which are currently supported. Preambles for SMPTE and ITU modes are identical. Extension of preamble to  $12$  bits is also supported.

**Table 31-1:** Video Mode Comparison

| Video Mode     | Frame Rate | Frame Resolution | Active Video Resolution | Sampling Frequency (MHz) | Remarks         |
|----------------|------------|------------------|-------------------------|--------------------------|-----------------|
| ITU 656 (NTSC) | 30         | 1716x525         | 720x480                 | 27.2                     | Y-C interleaved |
| ITU 656 (PAL)  | 25         | 1728x625         | 720x576                 | 26.8                     | Y-C interleaved |
| SMPTE 296M     | 30         | 3300x750         | 1280x720                | 74.25                    | Y,C separate    |
|                | 60         | 1650x750         | 1280x720                | 74.25                    | Y,C separate    |
| SMPTE 274M     | 30         | 2200x1125        | 1920x1080               | 74.25                    | Y,C separate    |
|                | 60         | 2200x1125        | 1920x1080               | 148.5                    | Y,C separate    |
|                | 25         | 2640x1125        | 1920x1080               | 74.25                    | Y,C separate    |
|                | 50         | 2640x1125        | 1920x1080               | 148.5                    | Y,C separate    |
|                | 24         | 2750x1125        | 1920x1080               | 74.25                    | Y,C separate    |

The EPPI supports all SMPTE modes shown above which run at a sampling frequency not higher than 74.25 MHz.

## EPPI Register List

The EPPI is a half-duplex, bidirectional port accommodating up to 16 bits of data. It has a dedicated clock pin and three multiplexed frame sync pins. The highest system throughput is achieved with 8-bit data, since two 8-bit data samples can be packed as a single 16-bit word. In such a case, the earlier sample is placed in the 8 least significant bits (LSBs). For more information on EPPI functionality, see the EPPI register descriptions.

**Table 31-2:** EPPI Module Registers

| Name      | Description                        |
|-----------|------------------------------------|
| EPPI_STAT | Status Register                    |
| EPPI_HCNT | Horizontal Transfer Count Register |
| EPPI_HDLY | Horizontal Delay Count Register    |

**Table 31-2:** EPPI Module Registers (Continued)

| Name           | Description                                                             |
|----------------|-------------------------------------------------------------------------|
| EPPI_VCNT      | Vertical Transfer Count Register                                        |
| EPPI_VDLY      | Vertical Delay Count Register                                           |
| EPPI_FRAME     | Lines Per Frame Register                                                |
| EPPI_LINE      | Samples Per Line Register                                               |
| EPPI_CLKDIV    | Clock Divide Register                                                   |
| EPPI_CTL       | Control Register                                                        |
| EPPI_FS1_WLHB  | FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register |
| EPPI_FS1_PASPL | FS1 Period Register / EPPI Active Samples Per Line Register             |
| EPPI_FS2_WLVB  | FS2 Width Register / EPPI Lines Of Vertical Blanking Register           |
| EPPI_FS2_PALPF | FS2 Period Register / EPPI Active Lines Per Field Register              |
| EPPI_IMSK      | Interrupt Mask Register                                                 |
| EPPI_ODDCLIP   | Clipping Register for ODD (Chroma) Data                                 |
| EPPI_EVENCLIP  | Clipping Register for EVEN (Luma) Data                                  |
| EPPI_FS1_DLY   | Frame Sync 1 Delay Value                                                |
| EPPI_FS2_DLY   | Frame Sync 2 Delay Value                                                |
| EPPI_CTL2      | Control Register 2                                                      |

## ADSP-BF60x EPPI Interrupt List

**Table 31-3:** ADSP-BF60x EPPI Interrupt List

| Description         | ID | DMA Channel | Sensitivity |
|---------------------|----|-------------|-------------|
| EPPI0 Channel 0 DMA | 98 | 29          | LEVEL       |

## EPPI Definitions

### ITU-R BT. 656

Description of a digital video protocol for interfaces and data stream format required to send uncompressed PAL or NTSC standard definition TV (525 or 625 lines) signals.

### YUV422

YUV is a color space where pixels are defined by a luminance (Y) component and chrominance (UV) components. The suffix signifies how the chrominance components have been decimated as well as formatting. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component are available. Typical YUV422 formatting interleaves the luminance and chrominance as such as U1Y1V1Y2U2Y3V2Y4.

### RGB888

RGB is a color space where pixels are defined by three color values; one red (R), one green (G) and one blue (B). The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green and blue value is 8-bits each.

### RGB565

RGB is a color space where pixels are defined by three color values; one red (R), one green (G) and one blue (B). The suffix signifies the bit widths for these color components. In this case, RGB565 means that

the red (R) and blue (B) are 5-bits each while the green (G) is 6-bits. When packed together, each RGB565 pixel can be represented in a 16-bit data word. This format is commonly used in LCD display panels.

### SMPTE 274M

An HD standard defining the spatial resolution (image sample structure) and frame rates for 1920x1080.

### SMPTE 296M

An HD standard for defining the spatial resolution (image sample structure) and frame rates from 1280x720.

## EPPI Block Diagram

The figure shows the functional blocks within the EPPI.

Figure 31-3: EPPI Block Diagram

## EPPI Architectural Concepts

This section describes EPPI architectural concepts, such as EPPI interface, reset operations frame syncs and sampling, DMA, PxP interface, and EPPI clock.

## EPPI Interface

The EPPI has a pixel pipe (PxP) interface in addition to the interface to the system crossbar. In transmit, the PxP interface is in the SCLK0 domain while in receive mode, the PxP interface is in the EPPI clock domain.

A block diagram of the architecture for the EPPI interface is shown below

**Figure 31-4:** EPPI DMA and PxP Interface

If the EPPI is configured for transmit, the Y channel data path can take data from either the YFIFO or the PxP interface. When configured to take data from the PxP interface, this PxP data is transmitted on the EPPI pins in all modes. When programmed to take data from the PxP, the DMACFG must be programmed as 0. Luma (and chroma) component should be made available only through the PxP interface. The control signals for deciding from which channel (DMA or PxP) the data is to be taken, is made available to the EPPI by the video subsystem block. When the EPPI is configured for PxP transmit, the incoming data and valid from the PxP are sampled on the SCLK and the outgoing Ready signal is driven on SCLK.

If the EPPI is configured for receive, the EPPI data can be transferred to either the PxP interface or the YFIFO or both. Here only the data going to DMA channel 1 is sent to the PxP. This could be either the Y data only (in split receive mode with EPPI\_CTL.DMACFG set) or the full EPPI input pin data in any other mode. If the EPPI is connected to the PIXC via the PxP, the EPPI can be programmed in a single DMA mode (EPPI\_CTL.DMACFG not set) so that the entire data from the pins of the EPPI flow through the YFIFO (dma channel 1). The control signals for deciding to which channel (DMA or PxP or to both) the data is to be transferred, is made available to the EPPI by the video subsystem block.

## Reset Operation

On a hardware reset, the entire EPPI is reset. All MMRs return to their default values. EPPI interrupt and DMA requests go inactive. Internally generated EPPI\_CLK and frame syncs are aborted.

In software, the EPPI can be reset and re-configured by writing 0 to the EN bit in the EPPI\_CTL register. When disabled in this manner, only the EPPI\_STAT register is cleared to its reset value and interrupts and DMA requests go inactive, and internally generated clock and frame syncs are aborted.

## Frame Sync Polarity and Sampling Edge

The POLS and POLC bits provide a mechanism to select the active level of the frame syncs and the sampling/driving edge of the EPPI clock, respectively. This allows the EPPI to connect to data sources and receivers with a wide array of control signal polarities. Often, the remote data source/receiver also offers configurable signal polarities; in these cases, the POLS and POLC bits add flexibility.

**Table 31-6:** Different Settings for POLS

|             | Frame Sync 2                | Frame Sync 1                |
|-------------|-----------------------------|-----------------------------|
| POLS = b#00 | Active high/ starts out low | Active high/ starts out low |
| POLS = b#01 | Active high/ starts out low | Active low/ starts out high |
| POLS = b#10 | Active low/ starts out high | Active high/ starts out low |
| POLS = b#11 | Active low/ starts out high | Active low/ starts out high |

**Table 31-7:** Different Settings for POLC

|                                            | RX           | TX                 |
|--------------------------------------------|--------------|--------------------|
| Drive Data Sample/Drive syncs              | Sample Data  | Sample/drive syncs |
| POLC = b#00<br>Rising edge<br>Rising edge  | Falling edge | Falling edge       |
| POLC = b#01<br>Rising edge<br>Falling edge | Falling edge | Rising edge        |
| POLC = b#10<br>Falling edge<br>Rising edge | Rising edge  | Falling edge       |

**Table 31-7:** Different Settings for POLC (Continued)

|              | RX          | TX          |
|--------------|-------------|-------------|
| POLC = b#11  | Rising edge | Rising edge |
| Falling edge |             |             |
| Falling edge |             |             |

## DMA

The EPPI has a native DMA controller with two channels. A local arbiter arbitrates between these channels. This arbitrated request is forwarded to the system crossbar. The EPPI would have only a single connection to the fabric.

**Figure 31-5:** EPPI DMA Interface

The EPPI must be used with DMA and configuring the EPPI DMA channels is a necessary step toward using the EPPI interface. The channels can be configured for either transmit or receive operation, and have a maximum throughput of  $(EPPI\_CLK) \times (32 \text{ bits/transfer})$ . In modes where data lengths permit, packing may be possible in order to increase transfer bandwidth. The highest throughput is achieved with 8-bit data and packing enabled.

The DMA engine generates interrupts at the completion of a row, frame, or partial-frame transfer. The DMA engine also coordinates the source or destination point for the data that is transferred through the EPPI.

The 2D DMA capability allows the processor to be interrupted at the end of a line or after a frame of video is transferred, or if a DMA error occurs. The `DMA_XCNT` and `DMA_YCNT` MMRs allows for flexible data inter-

rupt points. For example, assume the DMA registers  $\text{DMA\_XMOD} = \text{DMA\_YMOD} = 1$ . If a data frame contains  $320 \times 240$  bytes (240 rows of 320 bytes each), the following conditions hold.

- Setting  $\text{DMA\_XCNT} = 320$ ,  $\text{DMA\_YCNT} = 240$ , and  $\text{DISEL} = 1$  (the  $\text{DISEL}$  bit is located in  $\text{DMA\_CFG}$  register) interrupts on every row transferred, for the entire frame.
- Setting  $\text{DMA\_XCNT} = 320$ ,  $\text{DMA\_YCNT} = 240$ , and  $\text{DISEL} = 0$  interrupts only on the completion of the frame (when 240 rows of 320 bytes have been transferred).
- Setting  $\text{DMA\_XCNT} = 38,400$  ( $320 \times 120$ ),  $\text{DMA\_YCNT} = 2$ , and  $\text{DISEL} = 1$  causes an interrupt when half of the frame is transferred, and again when the whole frame is transferred.

The following is the general procedure for setting up DMA operation with the EPPI.

1. Configure the DMA registers as appropriate for the desired DMA operating mode.
2. Enable the DMA channel for operation.
3. Configure appropriate EPPI registers.
4. Enable the EPPI by writing a 1 to bit 0 in  $\text{EPPI\_CTL}$ .

## Pixel Pipe Interface (PxP)

The EPPI has a pixel pipe (PxP) interface in addition to the SCB interface to the fabric. In transmit, the PxP interface is in the SCLK domain while in receive, the interface is in the EPPI clock domain.

If the EPPI is configured for transmit, the Y channel data path can take data from either the YFIFO or the PxP Crossbar. When configured to take the data from PxP crossbar, this PxP data is transmitted on the EPPI pins in all modes. When programmed to take data from the PxP, the  $\text{DMACFG}$  register must be programmed to 0. Luma (and Chroma) components should be made available only through PxP. The video subsystem blocks (VSS) determine the control signals for deciding the channel (DMA or PxP) from which the data is taken. Refer to the video subsystem section for details.

When the EPPI is configured for PxP transmit, the incoming data and valid signal from the PxP are sampled on the SCLK and the outgoing ready signal is driven on SCLK. This implies the PIXC has to drive out the data in SCLK. The EPPI block with the pixel pipe addition is shown below.

**Figure 31-6:** EPPI Block with the Pixel Pipe Addition

If the EPPI is configured for receive, the EPPI data can be transferred to either the PxP crossbar or the YFIFO or both. Here, only the data going to DMA channel 1 is sent to the PxP. This could be either the Y data only (in split receive mode with  $DMACFG = 1$ ) or the full EPPI input pin data in any other mode. If the EPPI is connected to the PIXC via the PxP, the EPPI can be programmed in a single DMA mode ( $DMACFG = 0$ ) so that the entire data from the pins of the EPPI flows through the Y FIFO (DMA channel 1). The control signals for deciding to which channel (DMA or PxP or to both) the data is to be transferred, is made available to the EPPI by video subsystems block. Refer to the video subsystem section for details.

The following figures describe the design level details of how the PxP interface is multiplexed with the existing data path in transmit and receive case.

**Figure 31-7:** Receive Data Path with PxP Interface Muxing

**Figure 31-8:** Transmit Data Path with PxP Interface Muxing

## EPPI Clock

The EPPI can be supplied with an external clock, or the clock can be generated internally and supplied to external devices. When using the internal clock, the maximum frequency possible for EPPI\_CLK is SCLK/2. When using an external clock, the maximum frequency for EPPI\_CLK is 75 MHz.

When using an external EPPI\_CLK, there may be up to two cycles latency before valid data is received or transmitted.

The internal clock can be generated from SCLK if EPPI\_CTL.ICLKGEN is set. The generated clock frequency is then determined by the value in the EPPI\_CLKDIV register. The internally generated EPPI clock frequency is:

$$f_{PCLK} = f_{SCLK} / (CLKDIV + 1)$$

where:

$f_{PCLK}$  – frequency of internally generated EPPI Clock

$f_{\text{SCLK}}$  – frequency of SCLK

CLKDIV - Clock division value programmed in the EPPI\_CLKDIV register.

A few examples are given in the table below.

**Table 31-8:** Relationship Between CLKDIV and the Ratio of SCLK to EPPI Clock

| CLKDIV15-0 | SCLK:EPPI Clock Ratio |
|------------|-----------------------|
| DIV        |                       |
| 0x0002     | 1:3                   |
| 0x0003     | 1:4                   |
| 0x0002     | 1:3                   |
| 0x0003     | 1:4                   |
| ...        | ...                   |

## EPPI Operating Modes

The Enhanced Parallel Peripheral Interface (EPPI) supports various receive and transmit modes of operation which include the detection and generation of preamble data. Specifically, the EPPI supports data formats described in the specifications ITU-656, SMPTE 274M and SMPTE 296M. In addition to these modes, the EPPI also supports general purpose receive and transmit using up to three frame syncs (FS).

### ITU-R 656 Modes

The EPPI supports three input modes and one output mode for ITU-R 656 framed data. These modes are described in this section.

### ITU-R 656 Background

In ITU-R 656 (formerly known as CCIR-656) mode, the horizontal (H), vertical (V), and field (F) signals are sent as an embedded part of the video data stream in a series of bytes that form a control word.

The letter H is used to distinguish between the start of active video (SAV) and end of active video (EAV) signals, which indicate the beginning and end of active video data in each line. SAV occurs on a 1-to-0 transition of H, and EAV occurs on a 0-to-1 transition of H. The space between EAV and SAV is filled with horizontal blanking data. Therefore H = 1 during the horizontal blanking portion of the data stream and H = 0 during the active video portion of the data stream.

The letter V is used to denote the vertical blanking portion of the data stream. A transition in V can occur only in the EAV sequence. When  $V = 1$ , the data stream contains vertical blanking data and when  $V = 0$ , the data stream contains active video data.

The letter F is used to distinguish Field 1 from Field 2. Interlaced video has two fields in a frame of data. It requires each field to be handled uniquely, and alternate rows of each field combined to create the actual video image.

For interlaced video,  $F = 0$  represents Field 1 (“Odd Field”) and  $F = 1$  represents Field 2 (“Even Field”). Progressive video makes no distinction between Field 1 and Field 2, and F is always 0 for progressive video. Interlaced video requires each field to be handled uniquely, because alternate rows of each field combine to create the actual video image.

An entire field of video is comprised of active video plus horizontal blanking (the space between an EAV and SAV code) and vertical blanking (the space where  $V = 1$ ). A field of video commences on a transition of the F bit.

**Figure 31-9:** Typical Video Frame Partitioning for NTSC/PAL Systems in Interlaced and Progressive ITU-R BT.656 Systems

Figure 31-10: ITU-R 656 8-Bit Parallel Data Stream fro NTSC (PAL) Systems

Note there is a defined preamble of three data elements (for example, in the case of 8-bit video: 0xFF, 0x00, 0x00), followed by the XY status word, which, aside from the F (field), V (vertical blanking) and H (horizontal blanking) bits, contains four protection bits for error detection and correction. Note F and V are only allowed to change as part of EAV sequences (that is, transition from H = 0 to H = 1).

Table 31-9: Control Sequences for 8-Bit and 10-Bit ITU-R 656 Video

|              | 8-Bit Data |    |    |    |    |    |    |    | 10-Bit Data |    |
|--------------|------------|----|----|----|----|----|----|----|-------------|----|
|              | D9 (MSB)   | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1          | D0 |
| Preamble     | 1          | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1           | 1  |
|              | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0           | 0  |
|              | 0          | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0           | 0  |
| Control Byte | 1          | F  | V  | H  | P3 | P2 | P1 | P0 | 0           | 0  |

The bit definitions are as follows:

- F = 0 for field 1
- F = 1 for field 2
- V = 1 during vertical blanking
- V = 0 when not in vertical blanking
- H = 0 at SAV
- H = 1 at EAV
- $P3 = V \text{ XOR } H$
- $P2 = F \text{ XOR } H$

- $P1 = F \text{ XOR } V$
- $P0 = F \text{ XOR } V \text{ XOR } H$

P3–P0 are protection bits and enable 1 and 2-bit errors to be detected, and 1-bit errors to be corrected, at the receiver. The EPPI performs the correction if it detects 1-bit errors in F, V, or H. Errors in the protection bits themselves are detected but not corrected.

The EPPI\_STAT register contains two bits, ERRDET and ERRNCOR, used to report the status of error detected and error not corrected, respectively.

The ERRDET bit is set whenever an error is detected in the status word. However, this bit does not generate an interrupt. The ERRNCOR bit is set when more than a 1-bit error is detected in the status word. An interrupt is generated when the ERRNCOR bit is set. It can be cleared by clearing the ERRNCOR and ERRDET bits in the EPPI\_STAT register. Both bits are sticky and W1C.

In many applications, video streams other than the standard NTSC/PAL formats (for example, CIF, QCIF) can be employed. Because of this, the processor interface is flexible enough to accommodate different row and field lengths. In general, as long as the incoming video has the proper EAV/SAV codes, the EPPI can read it in. In other words, a CIF image could be formatted to be “656-compliant,” where EAV and SAV values define the range of the image for each line, and the V and F codes are used to delimit fields and frames.

The following sections provide descriptions of EPPI operations.

**Table 31-10:** Operating Modes and Generic EPPI Operation

|                 |               | How to configure                    | Useful for                                                             | How to configure in ITU R 656 TX Mode          |

## ITU-R 656 Input Modes

In the ITU-R 656 input modes, the clock CLK is either provided by the video source or supplied externally by the system.

There are three sub-modes supported for ITU-R 656 inputs: entire field, active video only, and vertical blanking interval only.

**Figure 31-11:** ITU-R 656 Input Sub-modes

## Entire Field

In this mode, the entire incoming bit stream is read in through the EPPI. This includes active video as well as control byte sequences and ancillary data that may be embedded in horizontal and vertical blanking intervals.

Data transfer starts immediately after synchronization to Field 1 occurs, but does not include the first EAV code that contains the  $F = 0$  assignment for interlaced video, or  $V = 0$  assignment for progressive video.

## Active Video

This mode is used when only the active video portion of a field is of interest, and not any of the blanking intervals. The EPPI ignores (does not read in) all data between EAV and SAV, as well as all data present when  $V = 1$ . In this mode, the control byte sequences are not stored to memory, they are filtered out by the EPPI. After synchronizing to the start of Field 1, the EPPI ignores incoming samples until it sees an SAV.

In active video mode, programs must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` MMR, and the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` MMR.

In this mode (as well as vertical blanking interval mode), any input data sequence that is considered as part of the preamble (for example in 8-bit ITU mode, 0xFF or 0x00 appearing in the input data stream are considered as part of the preamble) is not sent to memory, even if it appears individually, and is not tagged along with the preamble sequence FF, 00, 00.

## Vertical Blanking Interval (VBI)

In this mode, data transfer is only active while  $V = 1$  is in the control byte sequence. This indicates that the video source is in the midst of the Vertical Blanking Interval (VBI), which is sometimes used for ancillary data transmission. The ITU-R 656 recommendation specifies the format for these ancillary data packets, but the EPPI is not equipped to decode the packets themselves. This task must be handled in software. Horizontal blanking data is logged where it coincides with the rows of the VBI.

The VBI is split into two regions within each field. From the EPPI's standpoint, it considers these two separate regions as one contiguous space. However, keep in mind that frame synchronization begins at the start of Field 1, which doesn't necessarily correspond to the start of vertical blanking. For instance, in 525/60 systems, the start of Field 1 (F = 0) corresponds to line 4 of the VBI.

In VBI mode, the program must specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` MMR, and the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` MMR.

In this mode (as well as active video mode), any input data sequence that is considered as part of the preamble (for example in 8 bit ITU mode, 0xFF or 0x00 appearing in the input data stream are considered as part of the preamble) is not sent to memory, even if it appears individually, and is not be tagged along with the preamble sequence FF, 00, 00.

## ITU-R 656 Output in GP Transmit Modes

In GP transmit mode, the EPPI provides the ability to frame an ITU-R 656 output stream with the proper preambles and blanking intervals. This is done by setting the `BLANKGEN` bit in the `EPPI_CTL` register. The EPPI then only needs to fetch active data from memory through the DMA channel, saving DMA bandwidth. The `EPPI_FS1_PASPL`, `EPPI_FS2_WLVB`, `EPPI_FS2_PALPF` and `EPPI_FS1_WLHB` registers need to be programmed correctly in order for the EPPI to internally generate and embed the proper preamble, status word (EAV and SAV sequences) and blanking data along with the active video from memory. The EPPI can also drive out the frame syncs based on the `FSCFG` setting in the `EPPI_CTL` register.

The figure below shows the bit stream format in 16-bit transmit modes with blanking generation (BLANKGEN enabled). Each 16-bit data sample consists of 8-bit luma (Y) and 8-bit chroma (Cr or Cb) components. During transmission, the chroma data and the 0x80 blanking bytes are on the upper half (MSBs) of the data lines while the luma data and the 0x10 blanking bytes are on the lower half (LSBs) of the data lines.

**Figure 31-12: 16-Bit Transmit with Internal Blanking Generation**

The following figure shows the data transmitted by the EPPI in this mode. After the EPPI is enabled and if the EPPI FIFO is not empty, the transmission starts by sending out a EAV sequence for a vertical blanking line. For interlaced video, F starts at 1. For progressive video, F is always 0.

**NOTE:** Internal blanking generation functionality is valid only when the data length is 8, 10, or 16 bits and when the EPPI is in GP transmit modes. The `BLANKGEN` bit generates preambles even in GP 2FS mode.

The ITU-R 656 Output mode's internal blanking generation functionality can also be bypassed (for instance, if sending ancillary data in the blanking interval) by clearing the `BLANKGEN` bit in the `EPPI_CTL` register. The `BLANKGEN` bit generates preambles even in GP 2FS mode.

**Figure 31-13:** Generated Blanking Preamble Sequence

## Frame Synchronization in ITU-R 656 Modes

For interlaced video, the start of frame synchronization occurs when a high-to-low transition is detected in `F`, the field indicator. For progressive video, the start of frame synchronization occurs when a high-to-low transition is detected in `V`, the vertical blanking indicator. These transitions in `F` and `V` can occur only in the `EAV` sequence. A start of line is detected on a low-to-high transition in `H`, the horizontal blanking indicator, and this happens in the `EAV` sequence as well.

For interlaced video, the start of frame corresponds to the start of field 1. Consequently, up to two fields may be ignored (for example, if field 1 started before the EPPI-to-camera channel was established) before

data is received into the EPPI. For progressive video, the start of frame corresponds to the start of active video.

Because all H and V signaling is embedded in the data stream in ITU-R 656 modes, the count registers (EPPI\_HCNT, EPPI\_VCNT) are ignored. However, the EPPI\_FRAME register is still used to check for synchronization errors. Therefore, this MMR must be programmed with the number of lines expected in each frame of video. The EPPI keeps track of the number of EAV-to-SAV transitions that occur from the start of a frame until it decodes the end-of-frame condition (transition from F = 1 to F = 0 in the case of interlaced video and transition from V = 1 to V = 0 in the case of progressive video).

At this time, the actual number of lines processed is compared against the value in EPPI\_FRAME. If there is a mismatch, a frame track error is asserted in the EPPI\_STAT register. For instance, if an SAV transition was missed, the current field only has NUM\_ROWS – 1 rows, but re synchronization occurs at the start of the next frame. When the entire field is received, the field status bit is toggled in the EPPI\_STAT register. This way, an interrupt service routine (ISR) can discern which field was just read in.

## Ignoring Premature External Frame Syncs for Data Consistency

The relationship between the frame sync (FS) and the amount of data sent to memory is maintained even if frame syncs occur prematurely, whether due to data loss or an errant frame sync.

## General-Purpose EPPI Modes

The general-purpose (GP) EPPI modes are intended to suit a wide variety of data capture and transmission applications. Each EPPI has three bidirectional frame sync pins. Frame syncs can be generated internally by the EPPI, or by an external device communicating with the EPPI.

GP modes can be distinguished based on the number of frame syncs used. The EPPI supports the following GP modes:

- GP 0 FS mode
- GP 1 FS mode
- GP 2 FS mode
- GP 3 FS mode

All the GP modes, except 0 FS mode, support horizontal windowing. GP modes with 2 and 3 frame syncs also support vertical windowing.

For GP TX modes with internal clock or internal frame syncs, the EPPI starts generating the clock or frame syncs only when the EPPI FIFO is full for the first time. For GP 0 FS TX mode, the EPPI only starts transmitting when the EPPI FIFO is full for the first time.

## GP 0 FS Mode

This mode is useful for applications where periodic frame syncs are not used to frame the data.

GP 0 FS receive mode is further divided into two sub-modes; internal trigger ( $FLDSEL = 1$ ) and external trigger ( $FLDSEL = 0$ ), based on how data transmission/reception is initiated. GP 0 FS transmit mode is always internally triggered. All subsequent data manipulation is handled through DMA.

After initial trigger, the EPPI receives/transmits data samples on every clock cycle. However, if the `SKIPEN` bit is set for receive mode, the EPPI receives only alternate data samples.

The `EPPI_LINE`, `EPPI_FRAME`, `EPPI_HCNT`, `EPPI_HDLY`, `EPPI_VCNT` and `EPPI_VDLY` registers are not valid for GP 0 FS mode. Therefore windowing is not possible in this mode. Also, line and frame track errors are not applicable in this mode.

## Frame Synchronization in GP 0 FS External Trigger Mode

When the EPPI is programmed in external trigger mode, it does not generate the `EPPI_FS1` signal and a trigger must be provided by the external device. The EPPI starts receiving the data as soon as an `EPPI_FS1` signal assertion is detected. After that, all subsequent data manipulation is handled by way of DMA and any activity on `EPPI_FS1` is ignored.

## Frame Synchronization in GP 0 FS Internal Trigger Mode

When the EPPI is programmed in internal trigger mode, it starts receiving/transmitting data as soon as the EPPI clock is enabled and synchronized. When the EPPI is programmed in internal trigger mode, the EPPI starts receiving/transmitting data as soon as the EPPI clock is enabled and synchronized.

There may be up to two cycles latency before valid data is received or transmitted.

## GP 1 FS Mode

This mode is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs) and other general- purpose devices. This mode works for both transmit and receive.

The `EPPI_FRAME`, `EPPI_VDLY` and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

## GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, `HSYNC` and `VSYNC`. The `HSYNC` can be connected to `EPPI_FS1` and `VSYNC` can be connected to `EPPI_FS2`.

## DEN functionality in GP 2 FS Transmit Mode

When the EPPI is configured in GP 2 FS TX mode and when the EPPI is configured for internal frame sync generation, with EPPI\_CTL.MUXSEL and EPPI\_CTL.CLKGATEN bits no enabled, the EPPI\_FS3 pin functions as a data enable (DEN) pin. The functionality of the DEN pin is described in the following two cases.

Case 1 – When blanking generation (BLANKGEN) is enabled and the EPPI data length (DLEN) is configured for 8, 10, or 16-bit transfers, the EPPI\_FS3 pin asserts during the “active data” regions, aligned with EPPI\_CLK according to the clock polarity (POLC) settings. For this mode EPPI\_FS3 will be driven based on the POLC setting (i.e. EPPI\_FS3 will be driven out on the same EPPI clock edge that drives out data). The frame sync polarity (POLS) setting does not apply here— EPPI\_FS3 is always active high in this mode.

Case 2 – When blanking generation (BLANKGEN) is disabled, or it is enabled but the EPPI data length (DLEN) is configured for a transfer size different from 8, 10, or 16-bits, the EPPI\_FS3 pin asserts at the start of the active data region on each line, aligned with EPPI\_CLK according to the POLC settings. For this mode EPPI\_FS3 will be driven based on the POLC setting (i.e. EPPI\_FS3 will be driven out on the same EPPI clock edge that drives out data).

The POLS setting does not apply here -- EPPI\_FS3 is always active high in this mode. Once asserted, EPPI\_FS3 stays asserted for EPPI\_HCNT number of clock cycles per line, then it deasserts. This behavior on each line continues for the total number of lines programmed in the EPPI\_VCNT register per frame, and repeats at the start of subsequent video frames.

In case 2, if transmission of valid data is held off due to delays programmed in the EPPI\_HDLY and/or EPPI\_VDLY registers, the assertion of EPPI\_FS3 is also held off accordingly, on a per-line and/or per-frame basis.

## GP 3 FS Mode

This mode is useful for video applications that use three hardware synchronization signals, HSYNC, VSYNC, and FIELD. The HSYNC can be connected to the EPPI\_FS1 pin, VSYNC can be connected to the EPPI\_FS2 pin, and FIELD can be connected to the EPPI\_FS3 pin.

GP 3 FS mode is similar in operation to GP 2 FS mode, except that the start of frame synchronization in GP 3 FS mode also takes into account the EPPI\_FS3 pin. All the windowing register settings (EPPI\_FRAME, EPPI\_LINE, EPPI\_HDLY, EPPI\_HCNT, EPPI\_VDLY and EPPI\_VCNT), as well as data reception/transmission and error generation are the same as for GP 2 FS mode. In addition, for GP 3 FS mode with internal frame syncs, the FLDSEL bit setting in the EPPI\_CTL register specifies the condition under which the transfer should begin.

FS3 is generated by the EPPI and toggles during every assertion of FS2 or a combination of FS2 and FS1 (depending on the FLDSEL bit in the EPPI\_CTL register). The EPPI skips an FS2 if the FS3 value is high. Because of this condition, as a programming guideline, the FS2 period value should be half of the total number of pixels in the frame in 3 FS mode. When in 2FS mode, FS2 period should be programmed with the value equal to the number of pixels per frame.

## Supported Data Formats

The following sections describe EPPI receive and transmit data formats.

### EPPI Receive Data Format

**Table 31-11:** EPPI Receive Data Format

| Input Data Width | Usage Model   | Splitting/Packing Options                                                                                                                                                                                                                                                                                                        |
|------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8                | NTSC/PAL data | SPLTEO = 1<br>SUBSPLTODD = 1 if required to separate chroma components                                                                                                                                                                                                                                                           |
|                  | RGB sensor    | No splitting possible.<br>PACKEN = 1; Four EPPI words are packed to 32bit DMA data.<br>PACKEN = 0; Each EPPI word is sent as an 8bit data on the 32bit DMA bus. This would consume 4 times the DMA bandwidth of the 8bit case with PACKEN = 1;                                                                                   |
|                  | ADCs          | Gives I (in phase) and Q (quadrature) components.<br>SPLTEO = 1<br>SUBSPLTODD = 0 since there are only two components.                                                                                                                                                                                                           |
| 10               | NTSC/PAL data | Each EPPI word is zero filled/sign extended to 16bits.<br>SPLTEO = 1.<br>SUBSPLTODD = 1 if required to separate chroma components.                                                                                                                                                                                               |
|                  | RGB sensor    | No splitting possible.<br>PACKEN = 1; Two EPPI words are zero filled/sign extended to 16 bits and packed to 32bit DMA data.<br>PACKEN = 0; Each EPPI word may be zero filled/sign extended to 16 bits and sent as a 16 bit data on the 32bit DMA bus. This would consume double the bandwidth of the 10bit case with PACKEN = 1; |
|                  | ADCs          | Each EPPI word is zero filled/sign extended to 16 bits.<br>SPLTEO = 1<br>SUBSPLTODD = 0 since there are only two components.                                                                                                                                                                                                     |

**Table 31-11:** EPPI Receive Data Format (Continued)

## EPPI Data Transfer Modes

The following sections describe EPPI data transfer modes, including receive/transmit data packing, sign extension, zero fill, receive/transmit split modes, clock gating, delayed start, and data consistency management.

### Data Packing for Receive Modes

For receive modes, if `EPPI_CTL.PACKEN = 1` and the DMA is a 32-bit DMA, the EPPI packs the incoming data into 32-bit words based on the `DLEN` and `SWAPEN` bit settings. When `SWAPEN = 0`, the EPPI puts the

first data in the least significant bits and when `SWAPEN = 1`, the EPPI puts the first data in the most significant bits. The packing options for the `DLEN` bits are as follows.

- When `DLEN = 8`, four 8-bit words can be packed into one 32-bit word.
- When `DLEN = 16`, two 16-bit words can be packed into one 32-bit word.
- For `DLEN` values that are more than 8 bits but less than 16 bits, two such words are either sign-extended or zero-filled to 16 bits, and packed into one 32-bit word.
- When `DLEN = 18`, the EPPI sign-extends or zero-fills the 18-bit data to 24 bits and packs four 24-bit words into three 32-bit words.
- When `DLEN = 24`, the EPPI packs four 24-bit words into three 32-bit words.

When `EPPI_CTL.PACKEN = 0`, the EPPI receives the incoming data and sends it on the bus as-is. If `DLEN` is less than or equal to 16 bits, the DMA is a 16-bit DMA; otherwise it is a 32-bit DMA.

## Data Packing for Transmit Modes

For transmit modes, if `EPPI_CTL.PACKEN = 1` and the DMA is a 32-bit DMA, the EPPI unpacks the 32-bit word according to the `DLEN` and `SWAPEN` bit settings.

If `SWAPEN = 1`, the EPPI transmits the most significant bits as the first data, and if `SWAPEN = 0`, the EPPI transmits the least significant bits as the first data. The unpacking options for the `DLEN` bits are as follows.

- When `DLEN = 8`, the EPPI transmits one 32-bit word from memory as four 8-bit data words.
- For `DLEN` values greater than 8 bits but less than or equal to 16 bits, the EPPI transmits one 32-bit word from memory as two 16-bit data words.
- When `DLEN = 18` or `DLEN = 24`, the EPPI transmits three 32-bit words from memory as four data words.

## Sign-Extension and Zero-Filling

The following list describes the bit settings and functionality for sign-extension and zero-fill.

- For `DLEN` equal to 10, 12 or 14, data is zero-filled or sign-extended to 16 bits.
- For `DLEN` equal to 18 bits, data is zero-filled or sign-extended to 24 bits if packing is enabled, and zero-filled or sign-extended to 32 bits if packing is disabled.
- For `DLEN` equal to 24 bits, data is zero-filled or sign-extended to 32 bits if packing is disabled.
- For `DLEN` equal to 8 bits, data is zero-filled or sign-extended to 16 bits if packing is disabled.
- If the `EPPI_CTL.SIGNEXT` bit is set (`SIGNEXT = 1`), then the data is sign-extended, otherwise it is zero-filled.

## Split Receive Modes

The EPPI\_CTL register has three control bits for Split Receive modes. These are SPLTE0, SUBSPLTODD and DMACFG. Packing is not valid in Split modes.

- If SPLTE0 is set, the EPPI splits the incoming data stream into two sub-streams, an even stream and an odd stream, and packs them separately.
- The SUBSPLTODD bit is available only when SPLTE0 is set. In this case, when SUBSPLTODD is set, the EPPI sub-splits the odd sub-stream, and packs the streams separately.
- The DMACFG bit is also available only if SPLTE0 is set. In this case if DMACFG is set, the EPPI uses two DMA channels and if DMACFG is cleared, the EPPI uses only one DMA channel.

## Split Transmit Modes

The EPPI\_CTL register has three control bits for Split Transmit modes. These are SPLTE0, SUBSPLTODD and DMACFG. The DMA is always a 32-bit DMA. Packing is not valid in Split modes.

- If SPLTE0 is set, the EPPI receives the Luma (Y3Y2Y1Y0) and interleaved Chroma (Cr1Cb1Cr0Cb0) data as 32 bits from the DMA channel and interleaves the data to form a 4:2:2 YCrCb data stream to transmit.
- The SUBSPLTODD bit is available only when SPLTE0 is set. In this case if SUBSPLTODD is set, the EPPI receives the Luma (Y3Y2Y1Y0) and de-interleaved Chroma (Cb3Cb2Cb1Cb0 and Cr3Cr2Cr1Cr0) and interleaves the data to form a 4:2:2 YCrCb data stream to transmit. (Note that the EPPI does not de-interleave the chroma data when formatting it into 4:2:2)
- DMACFG is also valid only if SPLTE0 is set. If DMACFG is set, the EPPI uses two DMA channels and if DMACFG is cleared, the EPPI uses only one DMA channel.

## Clock Gating

In ITU-R BT.656 and GP 0/1/2 FS modes, EPPI\_FS3 becomes a clock-gating input. This is valid for both internally and externally sourced EPPI\_CLK, in both RX and TX modes. This clock gating signal must be synchronous with EPPI\_CLK and must be driven by the external device on the rising edge of EPPI\_CLK. Its function is to hold the sync and data lines in their current state until EPPI\_FS3 is driven low. There are no additional latency cycles upon coming out of clock gating mode.

If clock gating is not required, the EPPI\_FS3 pin must either be tied to ground, or configured to operate as another of its multiplexed functions.

In GP 2 FS transmit mode with internally generated frame syncs, the EPPI\_FS3 pin functions as a data enable (DEN) pin.

## Support for Delayed Start of EPPI Frame Syncs

The EPPI supports a delayed start of the EPPI frame syncs—PPIx\_FS1 and PPIx\_FS2. The PPIx\_FS1D and PPIx\_FS2D registers are programmable registers corresponding to PPIx\_FS1 (HSYNC) and PPIx\_FS2 (VSYNC). These registers are described below.

The first active edge of the internally generated frame sync is delayed by the amount programmed in these registers starting from the first PPI\_CLK edge. The delay counter (which is the period counter itself, since they don't run together) runs only for the first time and then shuts off until the EPPI is re-enabled. The delay registers should be programmed prior to the first PPI\_CLK edge (similar to the width and period registers). The figure below shows the functioning of PPI\_FS1 and PPI\_FS2.

**Figure 31-14:** EPPI Delayed Frame Sync Generation

## Ignoring Premature External Frame Syncs for Data Consistency

Once a frame has started with a VSYNC followed by a HSYNC (or both coming together), a line is tracked. When the count expires, the state machine waits at the end of line for a HSYNC to come. With the arrival of the HSYNC, the state machine starts tracking the next line and so on.

The number of lines tracked is counted separately and once the end of a frame is reached, the state machine waits there for the next VSYNC/HSYNC combination and the next frame starts once they are sampled. The problem with this scheme is that every incoming FS (VSYNC or HSYNC) resets the respective counters and the tracking starts all over (even if the FS signals are premature). This results in incomplete data (or frames) to enter into memory through the PxP interface.

To correct this problem, the EPPI waits for a frame/line completion before considering any incoming FS as valid as described below.

- Single FS mode and line tracking in dual FS mode – When a line is in progress, if HSYNC is detected prematurely, it is ignored. A line track underflow event is generated.
- Dual FS mode – If a VSYNC is received when a frame is in progress, it is ignored. A Frame Track Underflow error (FTERRUNDR) is generated.

Ignoring the FS ensures that once a frame starts, the amount of data that goes into the memory/PxP interface exactly corresponds to the programmed data size in a frame.

**NOTE:** Even if the premature FS is a valid FS, the state machine loses at most one frame and it recovers in the subsequent FS. At all times the FS to number of data going into the memory relationship is maintained as programmed.

When data underflow errors occur at the DMA interface, the EPPI does the following.

- If a premature line sync is detected, a LT underflow error is generated. All further line track errors are ignored until a next valid line sync is detected by the EPPI.
- If a premature frame sync is detected, a FT underflow error is generated. All further frame track and line track errors are ignored until a next valid frame sync is detected by the EPPI.

## EPPI Event Control

The following sections describe how events are used in EPPI management.

## EPPI Status, Error and Interrupt Signals

The EPPI generates an error interrupt if any one of the following error conditions occur.

- YFIFOERR (YFIFO underflow or overflow)
- CFIFOERR (CFIFO underflow or overflow)
- LTERROVR (line track overflow error)
- LTERRUNDR (line track underflow error)
- FTERROVR (frame track overflow error)
- FTERRUNDR (frame track underflow error)
- ERRNCOR (ITU preamble error not corrected)

These conditions are flagged in the EPPI\_STAT register and cleared by a W1C (write-1-to-clear) operation. Each of the individual conditions which cause an EPPI error interrupt can be masked. The interrupt mask register (EPPI\_IMSK) allows the masking of individual conditions which cause error interrupts.

There is only one interrupt line from each EPPI so all interrupts are internally OR'ed and sent as a single interrupt to the core. The EPPI\_STAT register must then be read to discover specific errors. These errors are described in detail in the following sections.

## PxP Errors

The following are PxP generated errors.

Receive Mode – The receive data sent to the PxP is stalled by the destination in EPPI receive. In this situation the data is lost because the EPPI cannot hold off the incoming data. This condition is reported in the `PXPERR` bit in the `EPPI_STAT` register. Cleared by a `W1C`.

Transmit mode – The transmit data coming from the PxP interface goes through the FIFO. Data underflow errors are reported as `YFIFOERR` if the FIFO underflows similar to the DMA transmit mode.

## Frame and Line Track Errors

When functioning in external frame sync mode, the `LTERROVR` (line track error), `LERRUNDR` (line track error), `FTERROVR` (frame track error) and `FTERRUNDR` (frame track error) status bits are used to keep track of the line and frame synchronization errors. They are updated when there is a mismatch in the H sync and V sync detected by the EPPI as compared to the programmed values in `PPIX_LINE` and `PPIX_FRAME` count registers.

## LTERROVR and LERRUNDR Errors

The line track overflow (`LTERROVR`) and underflow errors (`LERRUNDR`) generate an interrupt (which can be masked) as soon as they are identified (not at the next FS). If the FS has not arrived when the `EPPI_LINE` counter expires, then a `LTERROVR` is generated. When the `EPPI_LINE` counter is running and an FS is detected, the `LERRUNDR` is generated. Both interrupts are cleared by a `W1C`.

## FTERROVR and FTERRUNDR Errors

In the EPPI, the frame track overflow (`FTERROVR`) and underflow errors (`FTERRUNDR`) generate an interrupt (can be masked) as soon as they are identified. At the instance when `EPPI_FRAME` counter expires, if the FS has not arrived, then a `FTERROVR` is reported. It doesn't wait for the next FS to report this. When the `EPPI_FRAME` counter is running, if an FS is detected, then `LERRUNDR` is reported. Both these generate an error interrupt and should be cleared by a `W1C` at their respective locations in the status register.

A premature frame sync will result in a frame track under run error but the error will be logged (register bit set) only after the subsequent blanking period (if any) present.

## Preamble Error Not Corrected Error

The EPPI supports data embedded frame syncs in ITU and SMPTE formats. In these formats, the PPI could receive an erroneous preamble which is not correctable. `ERRNCOR` signals when this event occurs.

## EPPI Programming Model

The following sections describe programming techniques, including receiving/transmitting ITU-R 656 frames; configuring transfers in GP0, GP1, GP2, and GP3 modes; and managing EPPI mode configurations.

## Receiving ITU-R 656 Frames

The EPPI supports the reception of ITU-R 656 compliant frames.

1. Configure EPPI to receive either full ITU-R 656 frame, active video or blanking information by setting the `XFRTYPE` bits accordingly in the `EPPI_CTL` register.
2. In both active video mode and in VBI (vertical blanking information) mode, specify the number of total (active plus vertical blanking) lines per frame in the `EPPI_FRAME` register, and the number of total (active plus horizontal blanking plus 8) samples per line in the `EPPI_LINE` register.
3. Configure DMA descriptors to move the data to memory.
4. Enable DMA.
5. Enable EPPI.

*RESULT:*

Depending on how the EPPI is configured, either the full ITU-R 656 frame will be moved to memory or just the active video or just the blanking information.

## Transmitting ITU-R 656 Frames in GP Transmit Modes

The EPPI can take active video from memory and generate the proper preambles and blanking information to produce valid ITU-R 656 video frames for transmission.

1. Provide active data frame in memory.
2. Set `BLANKGEN` bit in `EPPI_CTL` register to have EPPI generate blanking information.
3. Configure `EPPI_FS1_WLHB`, `EPPI_FS1_PASPL`, `EPPI_FS2_WLVB`, `EPPI_FS2_PALPF` registers accordingly.
4. Configure rest of EPPI settings.
5. Configure DMA to fetch active frame data from memory buffers.
6. Enable DMA
7. Enable EPPI

*RESULT:*

The EPPI will take the active data from memory and generate the blanking information and transmit an ITU-R 656 frame

## Configuring Transfers in GP 0 FS Mode

The EPPI can be configured so no periodic frame syncs are used to frame the data.

1. Configure the EPPI to operate in GP 0 FS mode by setting `XFRTYPE = b#11` and `FSCFG = b#00` in the `EPPI_CTL` register.
2. When receiving, configure the EPPI to trigger on internally or externally by setting the `FLDSEL` field appropriately in the `EPPI_CTL` register. When transmitting, the trigger will always be internally generated.
3. Configure DMA to move the data to or from memory.
4. Enable DMA.
5. Enable EPPI.

*RESULT:*

The data amount of data transferred will be controlled by the DMA descriptions and not by any frame syncs from the EPPI.

## Configuring Transfers in GP 1 FS Mode

GP 1 FS modes is useful for interfacing the EPPI with analog-to-digital converters (ADCs), digital-to-analog converters (DACs) and other general-purpose devices. This mode works for both transmit and receive.

**NOTE:** The `EPPI_FRAME`, `EPPI_VDLY` and `EPPI_VCNT` registers have no effect in GP 1 FS mode. As a result, frame track errors and vertical windowing are not possible in this mode.

1. Configure the EPPI to operate in GP 1 FS mode by setting `XFRTYPE = b#11` and `FSCFG = b#01` in the `EPPI_CTL` register. The frame syncs may be provided by an external device or they can be sourced by the EPPI itself.
2. Program the `EPPI_LINE` register to contain the number clock cycles expected between two assertions of `EPPI_FS1`. This is used to keep track of Line Track errors. It must be programmed before the `EPPI_HCNT` register.
3. Program the `EPPI_HDLY` register to contain the number of clock cycles to wait after the assertion of `EEPX_FS1`, for example, start of frame.
4. Program the `EPPI_HCNT` register to contain the number of data samples to receive or transmit for each frame.
5. Configure DMA to move the data to or from memory.

6. Enable DMA.
7. Enable EPPI.

*RESULT:*

Data will be moved in or out of memory and framed by a frame sync for every line.

## Configuring Transfers in GP 2 FS Mode

GP 2 FS mode is useful for video applications that use two hardware synchronization signals, HSYNC and VSYNC. The HSYNC can be connected to EPPI\_FS1 and VSYNC can be connected to EPPI\_FS2.

1. Configure the EPPI to operate in GP 0 FS mode by setting `XFRTYPE = b#11` and `FSCFG = b#10` in the `EPPI_CTL` register. The frame syncs may be provided by an external device or they can be sourced by the EPPI itself.
2. Program the `EPPI_FRAME` register to contain the number of expected lines per frame. It should be equal to the number of EPPI\_FS1 assertions expected between start of frame syncs and is used to keep track of frame track errors. It must be programmed before the `EPPI_VCNT` register.
3. Program the `EPPI_LINE` register to contain the number of clock cycles expected between two assertions of EPPI\_FS1. This is used to keep track of line track errors. It must be programmed before the `EPPI_HCNT` register.
4. Program the `EPPI_HDLY` register to contain the number of clock cycles to wait after the assertion of EPPI\_FS1, for example, start of line.
5. Program the `EPPI_HCNT` register to contain the number of data samples to receive or transmit for each line.
6. Program the `EPPI_VDLY` register to contain the number of lines to wait after the start of frame is detected.
7. Program the `EPPI_VCNT` register to contain the number of lines to receive or transmit.
8. If setting up the EPPI for transmit, the data enable (`DEN`) pin will behave according to the enabling of the blanking generation and setting of data length (`DLEN`). More detail can be found at TBD.
9. Enable DMA
10. Enable EPPI.

*RESULT:*

Data will be moved in or out of memory and framed by a frame sync for every line and frame.

## Configuring Transfers in GP 3 FS Mode

GP 3 FS mode is useful for video applications that use three hardware synchronization signals, HSYNC, VSYNC, and FIELD. The HSYNC can be connected to EPPI\_FS1, VSYNC can be connected to EPPI\_FS2, and FIELD can be connected to EPPI\_FS3.

1. Configure the EPPI to operate in GP 0 FS mode by setting the `XFRTYPE = b#11` and `FSCFG = b#11` in the `EPPI_CTL` register. The frame syncs may be provided by an external device or they can be sourced by the EPPI itself.
2. Configure the windowing registers according to steps in GP 2 FS Mode.
3. Enable DMA.
4. Enable EPPI.

### *RESULT:*

Data will be moved in or out of memory and framed by a frame sync for every line and frame. Operation and result is similar to operation in GP 2 FS Mode but EPPI\_FS3 will also be taken into account.

## Configuring the EPPI to Use the Windowing Feature

Windowing is a useful feature for applications where the region of interest is smaller than the active video stream (for example, sensor calibration, auto-focusing, and others). It can result in significant DMA bandwidth reduction. The EPPI supports windowing for GP Input modes.

1. Program the `EPPI_FRAME` register with the number of lines the frame contains.
2. Program the `EPPI_LINE` register with the number of samples per line in the frame.
3. Program the `EPPI_VDLY` register with the number of lines to wait after the start of a new frame before starting to read/transmit data.
4. Program the `EPPI_VCNT` register with the number of lines to read in or write out after `EPPI_VDLY` number of lines from the start of the frame.
5. Program the `EPPI_HDLY` register with the number of clock cycles to delay after the assertion of `EPPI_FS1` is detected for the start of a new line.
6. Program the `EPPI_HCNT` register with the number of samples to read in or write out after `EPPI_HDLY` number of cycles have expired since the assertion of `EPPI_FS1`.

## EPPI Mode Configuration

This section describes EPPI mode configurations, including support for all EPPI transmit and receive modes.

### Configuring 8-Bit Receive Mode

For 8-bit non-split receive mode, if `EPPI_CTL.PACKEN = 1`, the EPPI packs four bytes of incoming data into a 32-bit word. Alternate even or odd samples may be skipped based on the `SKIPEN` and `SKIEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `SWAPEN` bit setting.

**Table 31-13:** 8-Bit Receive Mode with Packing Enabled

| Pin Data (8 bits) | DMA DATA<br>SKIPEN=0<br>SKIEO=X<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=0<br>SKIEO=X<br>SWAPEN=1<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIEO=1<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIEO=0<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIEO=1<br>SWAPEN=1<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIEO=0<br>SWAPEN=1<br>SIGNEXT=X |
|-------------------|----------------------------------------------------------|----------------------------------------------------------|----------------------------------------------------------|----------------------------------------------------------|----------------------------------------------------------|----------------------------------------------------------|

If PACKEN = 0, the DMA is a 16-bit DMA and the EPPI either sign-extends or zero-fills the bytes of incoming data into a 16-bit word. The SWAPEN bit has no effect if PACKEN = 0.

## Configuring 10/12/14-Bit Receive Modes

For 10, 12, or 14-bit non-split receive modes, the EPPI first either zero-fills or sign-extends the incoming data (depending on the SIGNEXT bit) into a 16-bit word. If PACKEN = 1, the EPPI then packs two of these words into one 32-bit word. Alternate even or odd samples may be skipped based on the SKIPEN and

SKIPEN bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the SWAPEN bit setting.

**Table 31-15:** 10-Bit Receive Mode with Sign Extension, with Packing Enabled

| Pin Data (10 bits) | MSB | DMA DATA<br>SKIPEN=0<br>SKIPEN=X<br>SWAPEN=0<br>SIGNEXT=1 | DMA DATA<br>SKIPEN=0<br>SKIPEN=X<br>SWAPEN=1<br>SIGNEXT=1 | DMA DATA<br>SKIPEN=1<br>SKIPEN=1<br>SWAPEN=0<br>SIGNEXT=1 |

## Configuring 16-Bit Receive Mode

For 16-bit non-split receive mode, if `PACKEN = 1`, the EPPI packs two 16-bit incoming data into one 32-bit word. Alternate even or odd samples may be skipped based on the `SKIPEN` and `SKIPEO` bits. The first incoming data can be placed either in the least significant bit positions or in the most significant bit positions, based on the `SWAPEN` bit setting.

**Table 31-19:** 16-Bit Receive Mode with Packing Enabled

| Pin Data (16 bits) | DMA DATA<br>SKIPEN=0<br>SKIPEO=X<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=0<br>SKIPEO=X<br>SWAPEN=1<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIPEO=1<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIPEO=0<br>SWAPEN=0<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIPEO=1<br>SWAPEN=1<br>SIGNEXT=X | DMA DATA<br>SKIPEN=1<br>SKIPEO=0<br>SWAPEN=1<br>SIGNEXT=X |

## Configuring 18-Bit Receive Mode

For 18-bit non-split receive mode, if `PACKEN = 0`, the EPPI zero-fills or sign-extends the incoming data into a 32-bit word. If `PACKEN = 1`, the EPPI first zero-fills or sign-extends the incoming data to 24 bits, and then packs four such 24-bit data words into three 32-bit words. Alternate even or odd samples may be skipped based on the `SKIPEN` and `SKIPEO` bits. The `SWAPEN` bit has no effect.

**Table 31-21:** 18-bit Receive Mode with Packing Disabled

| Pin Data (18 bits) | DMA DATA<br>SKIPEN=0<br>SKIPEO=X<br>SWAPEN=X<br>SIGNEXT=0 | DMA DATA<br>SKIPEN=1<br>SKIPEO=1<br>SWAPEN=X<br>SIGNEXT=0 | DMA DATA<br>SKIPEN=1<br>SKIPEO=0<br>SWAPEN=X<br>SIGNEXT=0 |

For the case when SPLTEO = 1, SUBSPLTODD = 1 and DMACFG = 0, note that although the second Chroma component (U<sub>0</sub>U<sub>1</sub>U<sub>2</sub>U<sub>3</sub> in the tables above) sent over the DMA bus is completely packed before the Luma component (Y<sub>4</sub>Y<sub>5</sub>Y<sub>6</sub>Y<sub>7</sub> in the tables above), it is intentionally held until that previous word is moved out. This allows the separation of Luma and Chroma values into individual buffers when using 2D-DMA.

### Configuring 10/12/14/16-Bit Split Receive Mode with SPLTWRD=0

For 16-bit split receive mode, PACKEN is not valid. The EPPI always packs two 16-bit words into one 32-bit word. For 10, 12, or 14-bit split receive modes, the EPPI first either sign-extends or zero-fills the incoming data into a 16 bit word, and then packs two of these words into one 32-bit word to send to the DMA.

### Configuring 16-Bit Split Receive Mode with SPLTWRD=1

For 16-bit split receive mode, PACKEN is not valid. The EPPI always packs two 16-bit words into one 32-bit word. The SPLTWRD bit is only valid when DLEN = 16 bits.

## Configuring 8-Bit Transmit Mode

For 8-bit non-split transmit mode, if PACKEN = 1, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into four bytes to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the SWAPEN bit setting. If PACKEN = 0, the DMA is a 16-bit DMA and the EPPI transmits the lower 8 bits. SWAPEN has no effect when PACKEN = 0.

**Table 31-30:** 8-bit Transmit Mode with Packing Enabled

| DMA Data (32 bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
| 0x11223344         | 0x44                   | 0x11                   |

**Table 31-30:** 8-bit Transmit Mode with Packing Enabled (Continued)

| DMA Data (32 bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
| 0x55667788         |                        | 0x33<br>0x22           |
|                    | 0x22                   | 0x33                   |
|                    | 0x11                   | 0x44                   |
|                    | 0x88                   | 0x55                   |
|                    | 0x77                   | 0x66                   |
|                    | 0x66                   | 0x77                   |
|                    | 0x55                   | 0x88                   |

**Table 31-31:** Data Sent in 8-bit Transmit Mode with Packing Disabled

| DMA Data (16 bits) | Pin Data SWAPEN=X |
|--------------------|-------------------|
| 0x1234             | 0x34              |
| 0x2345             | 0x45              |
| 0x3456             | 0x56              |

## Configuring 10/12/14-Bit Transmit Modes

For 10, 12, or 14-bit non-split transmit modes, if `PACKEN = 1`, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into two 16-bit data words, then transmits the required LSBs from each. The EPPI transmits either the most significant word or the least significant word as the first data, depending on the `SWAPEN` bit setting. If `PACKEN = 0`, the DMA is a 16-bit DMA and the EPPI transmits the required LSBs. The `SWAPEN` bit has no effect when `PACKEN = 0`.

**Table 31-32:** 10-bit Transmit Mode with Packing Enabled

| DMA Data (32 bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
| 0x1111 2222        | 0x222                  | 0x111                  |
| 0x3333 4444        | 0x111                  | 0x222                  |
|                    | 0x044                  | 0x333                  |

**Table 31-32:** 10-bit Transmit Mode with Packing Enabled (Continued)

| DMA Data (32 bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
|                    | 0x333                  | 0x044                  |

**Table 31-33:** 10-bit Transmit Mode with Packing Disabled

| DMA Data (16 bits) | Pin Data SWAPEN=X |
|--------------------|-------------------|
| 0x1234             | 0x234             |
| 0x2345             | 0x345             |
| 0x3456             | 0x056             |
| 0x4567             | 0x167             |

## Configuring 16-Bit Transmit Mode

For 16-bit non-split transmit mode, if `PACKEN = 1`, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory into two 16-bit data words to transmit. The EPPI transmits either the MSBs or the LSBs as the first data, depending on the `SWAPEN` bit setting. If `PACKEN = 0`, the DMA is a 16-bit DMA and the EPPI transmits the data as is. `SWAPEN` has no effect when `PACKEN = 0`.

**Table 31-34:** 16-bit Transmit Mode with Packing Enabled

| DMA Data (32 bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
| 0x1111 2222        | 0x2222                 | 0x1111                 |
| 0x3333 4444        | 0x1111                 | 0x2222                 |
|                    | 0x4444                 | 0x3333                 |
|                    | 0x3333                 | 0x4444                 |

**Table 31-35:** 16-bit Transmit Mode with Packing Disabled

| DMA Data (16 bits) | Pin Data SWAPEN=X |
|--------------------|-------------------|
| 0x1234             | 0x1234            |
| 0x2345             | 0x2345            |

**Table 31-35:** 16-bit Transmit Mode with Packing Disabled (Continued)

| DMA Data (16 bits) | Pin Data SWAPEN=X |
|--------------------|-------------------|
| 0x3456             | 0x3456            |

## Configuring 18-Bit Transmit Mode

For 18-bit transmit mode, if `PACKEN = 1`, the DMA is a 32-bit DMA and the EPPI unpacks the 32-bit word from memory. In this mode, when `RGB_FMT_EN` is set, the least significant two bits of R, G, and B are dropped.

**Table 31-36:** 18-bit Transmit Mode with Packing Enabled

| DMA Data    | Pin Data (18-bits) |            |
|-------------|--------------------|------------|
|             | RGBFMTEN=0         | RGBFMTEN=1 |
| 0x0123 4567 | 0x3 4567           | 0x0 8459   |
| 0x89AB CDEF | 0x1 EF01           | 0x3 3EC0   |
| 0x0123 4567 | 0x3 89AB           | 0x1 98AA   |
|             | 0x1 2345           | 0x0 0211   |

**Table 31-37:** 18-bit Transmit Mode with Packing Disabled

| DMA Data    | Pin Data (18-bits) |            |
|-------------|--------------------|------------|
|             | RGBFMTEN=0         | RGBFMTEN=1 |
| 0x0123 4567 | 0x3 4567           | 0x0 8459   |
| 0x89AB CDEF | 0x3 CDEF           | 0x2 ACFB   |
| 0x0123 4567 | 0x3 4567           | 0x0 8459   |

## Configuring 24-Bit Transmit Mode

For 24-bit transmit mode, if `PACKEN = 1`, the DMA is a 32-bit DMA and the EPPI unpacks three 32-bit words from memory into four 24-bit words to transmit. The effect of the `SWAPEN` bit setting is shown in the table below.

**Table 31-38:** 24-bit Transmit Mode

| DMA Data (32 Bits) | Pin Data when SWAPEN=0 | Pin Data when SWAPEN=1 |
|--------------------|------------------------|------------------------|
| $R_1B_0G_0R_0$     | $B_0G_0R_0$            | $R_0G_0B_0$            |
| $G_2R_2B_1G_1$     | $B_1G_1R_1$            | $R_1G_1B_1$            |
| $B_3G_3R_3B_2$     | $B_2G_2R_2$            | $R_2G_2B_2$            |
|                    | $B_3G_3R_3$            | $R_3G_3B_3$            |

## Configuring 8-Bit Split Transmit Mode

For 8-bit split transmit mode, `PACKEN` is not valid. The EPPI always unpacks the 32-bit DMA data into four bytes to transmit.

**Table 31-39:** 8-bit Split Transmit Mode with `SPLTEO=1`, `SUBSPLTODD=0` and `SWAPEN=0`

| DMACFG=1<br>DMACFG=0 |                     |                   |                     |                   |
|----------------------|---------------------|-------------------|---------------------|-------------------|

### Configuring 10/12/14/16-Bit Transmit Mode with SPLTWRD = 0

For 16-bit split transmit mode, PACKEN is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. For 10, 12, or 14-bit split transmit modes, the EPPI first unpacks the data in the same way as for 16-bit transmit mode, but transmits only the required number of LSBs.

**Table 31-43:** 16-bit Split Transmit Mode with SPLTEO = 1, SUBSPLTODD = 0, and SWAPEN = 0

| DMACFG = 1                    |                               |                    | DMACFG = 0                    |                    |

### Configuring 16-Bit Split Transmit Mode with SPLTWRD = 1

For 16-bit split transmit mode, PACKEN is not valid. The EPPI always unpacks the 32-bit DMA data into two 16-bit words to transmit. The SPLTWRD bit is only valid when DLEN = 16 bits.

**Table 31-47:** 16-bit Split Transmit Mode with SPLTWRD = 1, SUBSPLTODD = 0, and SWAPEN = 0

| DMACFG = 1          |                     |                    | DMACFG = 0          |                    |
|---------------------|---------------------|--------------------|---------------------|--------------------|
| DMA0 DATA (32 bits) | DMA1 DATA (32 bits) | Pin Data (16 bits) | DMA0 DATA (32 bits) | Pin Data (16 bits) |

## EPPI Programming Concepts

This section currently includes only SMPTE mode programming. The remaining content for this section is TBD.

### EPPI SMPTE Modes Programming

The programming model of SMPTE modes is similar to ITU Modes. All programming modes pertaining to ITU modes like XFRTYPE, FSCFG, FLDSEL and BLANKGEN hold true for SMPTE modes as well. The only difference is that since ITU modes use Y-Cr/Cb interleaved data and SMPTE use parallel Y-Cr/Cb

data, SPLTWRD should be set while operating in SMPTE modes. The following table describes the programming modes for different SMPTE formats.

**Table 31-49:** Programming Modes for SMPTE Formats

| SMPTE Format | SMPTE Channel Width | EPPI Input Bit Width                | EPPI Mode                    | Remarks                                               |
|--------------|---------------------|-------------------------------------|------------------------------|-------------------------------------------------------|

|              | 10                  | 20<br>Cr/Cb - [19:10]<br>Y - [9:0]  | DLEN = 20bits<br>SPLTWRD = 1 | SIGNEXT extends each channel data to the 16b boundary |

Note: EPPI Clock at 74.25MHz for all the above modes

## EPPI Register Descriptions

EPPI (EPPI) contains the following registers.

**Table 31-50:** EPPI Module Registers

| Name      | Description                        |
|-----------|------------------------------------|
| EPPI_STAT | Status Register                    |
| EPPI_HCNT | Horizontal Transfer Count Register |
| EPPI_HDLY | Horizontal Delay Count Register    |
| EPPI_VCNT | Vertical Transfer Count Register   |

**Table 31-50:** EPPI Module Registers (Continued)

| Name           | Description                                                             |
|----------------|-------------------------------------------------------------------------|
| EPPI_VDLY      | Vertical Delay Count Register                                           |
| EPPI_FRAME     | Lines Per Frame Register                                                |
| EPPI_LINE      | Samples Per Line Register                                               |
| EPPI_CLKDIV    | Clock Divide Register                                                   |
| EPPI_CTL       | Control Register                                                        |
| EPPI_FS1_WLHB  | FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register |
| EPPI_FS1_PASPL | FS1 Period Register / EPPI Active Samples Per Line Register             |
| EPPI_FS2_WLVB  | FS2 Width Register / EPPI Lines Of Vertical Blanking Register           |
| EPPI_FS2_PALPF | FS2 Period Register / EPPI Active Lines Per Field Register              |
| EPPI_IMSK      | Interrupt Mask Register                                                 |
| EPPI_ODDCLIP   | Clipping Register for ODD (Chroma) Data                                 |
| EPPI_EVENCLIP  | Clipping Register for EVEN (Luma) Data                                  |
| EPPI_FS1_DLY   | Frame Sync 1 Delay Value                                                |
| EPPI_FS2_DLY   | Frame Sync 2 Delay Value                                                |
| EPPI_CTL2      | Control Register 2                                                      |

## Status Register

The EPPI\_STAT register contains bits that provide information about the current operating state of the EPPI.

**EPPI\_STAT: Status Register - R/W**

Reset = 0x0000 0000

**Figure 31-15:** EPPI\_STAT Register Diagram

**Table 31-51:** EPPI\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                 |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | FLD      | Current Field Received by EPPI.<br>The <code>EPPI_STAT.FLD</code> bit indicates whether the current field being received by the PPI is Field 1 (if clear) or Field 2 (if set).                                                                                          |
|         |          | 0      Field 1                                                                                                                                                                                                                                                          |
|         |          | 1      Field 2                                                                                                                                                                                                                                                          |
| 14      | ERRDET   | Preamble Error Detected.<br>The <code>EPPI_STAT.ERRDET</code> bit is useful only in ITU receive modes and indicates if an error has been detected in the status word of EAV or SAV sequences (if set) or not (if clear).                                                |
|         |          | 0      No preamble error detected                                                                                                                                                                                                                                       |
|         |          | 1      Preamble error detected                                                                                                                                                                                                                                          |
| 7       | PXPERR   | PxP Ready Error.<br>The <code>EPPI_STAT.PXPERR</code> bit is valid only in the RX mode. This bit indicates whether the incoming PPI data overflows the PxP interface (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it. |

**Table 31-51:** EPPI\_STAT Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                    |
|---------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | ERRNCOR   | Preamble Error Not Corrected.<br>The <code>EPPI_STAT.ERRNCOR</code> bit is useful only in the ITU receive modes and indicates if an error in the status word of EAV or SAV sequences can not be cleared (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it. |
|         |           | 0      No uncorrected preamble error has occurred                                                                                                                                                                                                                                                          |
|         |           | 1      Preamble error detected but not corrected                                                                                                                                                                                                                                                           |
| 5       | FTERRUNDR | Frame Track Underflow.<br>The <code>EPPI_STAT.FTERRUNDR</code> bit indicates whether a frame track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.                                                                         |
|         |           | 0      No Error Detected                                                                                                                                                                                                                                                                                   |
|         |           | 1      Error Occurred                                                                                                                                                                                                                                                                                      |
| 4       | FTERROVR  | Frame Track Overflow.<br>The <code>EPPI_STAT.FTERROVR</code> bit indicates whether a frame track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.                                                                            |
|         |           | 0      No Error Detected                                                                                                                                                                                                                                                                                   |
|         |           | 1      Error Occurred                                                                                                                                                                                                                                                                                      |
| 3       | LTERRUNDR | Line Track Underflow.<br>The <code>EPPI_STAT.LTERRUNDR</code> bit indicates whether a line track underflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.                                                                           |
|         |           | 0      No Error Detected                                                                                                                                                                                                                                                                                   |
|         |           | 1      Error Occurred                                                                                                                                                                                                                                                                                      |

**Table 31-51:** EPPI\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                 |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | LTERROVR | Line Track Overflow.<br>The EPPI_STAT.LTERROVR bit indicates whether a line track overflow error has occurred (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.                                                                                                        |
|         |          | 0 No Error Detected                                                                                                                                                                                                                                                                                                     |
|         |          | 1 Error Occurred                                                                                                                                                                                                                                                                                                        |
| 1       | YFIFOERR | Luma FIFO Error.<br>For RX modes, the EPPI_STAT.YFIFOERR bit indicates whether the Luma FIFO has overflowed (if set) or not (if clear). For TX modes, this bit indicates whether the Luma FIFO has underflowed (if set) or not (if clear). This bit is sticky and must be cleared by software by writing 1 to it.       |

## Horizontal Transfer Count Register

The EPPI\_HCNT register holds the number of samples to read in or write out per line, after EPPI\_HDLY number of cycles have expired since the assertion of EPPI\_FS1. Any write to the EPPI\_LINE register modifies the EPPI\_HCNT register, but any write to EPPI\_HCNT does not affect the EPPI\_LINE register value. So, the EPPI\_HCNT register should be programmed after the EPPI\_LINE register.

EPPI\_HCNT: Horizontal Transfer Count Register - R/W

Reset = 0x0000 0000

Figure 31-16: EPPI\_HCNT Register Diagram

Table 31-52: EPPI\_HCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Horizontal Transfer Count.<br>The EPPI_HCNT.VALUE holds the number of samples to read in or write out per line, after EPPI_HDLY number of cycles have expired since the last assertion of EPPI_FS1. |

Horizontal Delay Count Register

The EPPI\_HDLY register contains the number of clock cycles to delay after the assertion of EPPI\_FS1 is detected before starting to read or write data.

EPPI\_HDLY: Horizontal Delay Count Register - R/W

Reset = 0x0000 0000

Figure 31-17: EPPI\_HDLY Register Diagram

**Table 31-53:** EPPI\_HDLY Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Horizontal Delay Count.<br>The EPPI_HDLY.VALUE holds the number of EPPI_CLK cycles to delay after assertion of EPPI_FS1 before starting to read or write data. |

## Vertical Transfer Count Register

The EPPI\_VCNT register holds the number of lines to read in or write out, after EPPI\_VDLY number of lines from the start of frame. Any write to the EPPI\_FRAME register modifies the EPPI\_VCNT register, but any write to EPPI\_VCNT does not affect the EPPI\_FRAME register value. So, the EPPI\_VCNT register should be programmed after the EPPI\_FRAME register.

**EPPI\_VCNT: Vertical Transfer Count Register - R/W**

Reset = 0x0000 0000

**Figure 31-18:** EPPI\_VCNT Register Diagram

**Table 31-54:** EPPI\_VCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Vertical Transfer Count.<br>The EPPI_VCNT.VALUE holds the number of lines to read in or write out, after EPPI_VDLY number of lines from the start of frame. |

## Vertical Delay Count Register

The EPPI\_VDLY register contains the number of lines to wait after the start of a new frame before starting to read/transmit data.

EPPI\_VDLY: Vertical Delay Count Register - R/W

Reset = 0x0000 0000

Figure 31-19: EPPI\_VDLY Register Diagram

Table 31-55: EPPI\_VDLY Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Vertical Delay Count.<br>The EPPI_VDLY.VALUE holds the number of lines to wait after the start of a new frame before starting to read/transmit data. |

Lines Per Frame Register

The EPPI\_FRAME register tracks the frame track overflow and underflow errors. This register should be programmed with the number of lines expected per frame. Any write to the EPPI\_FRAME register will also write the same value to the EPPI\_VCNT register, but any write to EPPI\_VCNT does not affect the EPPI\_FRAME register value. So, the EPPI\_FRAME register should be programmed before the EPPI\_VCNT register.

EPPI\_FRAME: Lines Per Frame Register - R/W

Reset = 0x0000 0000

Figure 31-20: EPPI\_FRAME Register Diagram

**Table 31-56:** EPPI\_FRAME Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Lines Per Frame.<br>The EPPI_FRAME.VALUE holds the number of lines expected per frame of data. |

## Samples Per Line Register

The EPPI\_LINE register tracks the line track overflow and underflow Errors. This register should be programmed with the number of samples expected per line. Any write to the EPPI\_LINE register will also write the same value to the EPPI\_HCNT register, but any write to EPPI\_HCNT does not affect the EPPI\_LINE register value. So, the EPPI\_LINE register should be programmed before the EPPI\_HCNT register.

### EPPI\_LINE: Samples Per Line Register - R/W

Reset = 0x0000 0000

**Figure 31-21:** EPPI\_LINE Register Diagram

**Table 31-57:** EPPI\_LINE Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                 |
|---------|----------|-----------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Samples Per Line.<br>The EPPI_LINE.VALUE holds the number of samples expected per line. |

## Clock Divide Register

The EPPI\_CLKDIV register provides the divisor for EPPI internal clock generation. The generated clock frequency is given by following formula:

$$\text{EPPI\_CLK} = (\text{SCLK}) / (2 * (\text{EPPI\_CLKDIV} + 1))$$

Note that a value of 0xFFFF is invalid for the EPPI\_CLKDIV register.

EPPI\_CLKDIV: Clock Divide Register - R/W

Reset = 0x0000 0000

Figure 31-22: EPPI\_CLKDIV Register Diagram

Table 31-58: EPPI\_CLKDIV Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | Internal Clock Divider. |

Control Register

The EPPI\_CTL register configures the EPPI for operating mode, control signal polarities, and data width of the port.

### EPPI\_CTL: Control Register - R/W

Reset = 0x0000 0000

Figure 31-23: EPPI\_CTL Register Diagram

**Table 31-59:** EPPI\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                   |                            |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| 31      | CLKGATEN | Clock Gating Enable.<br>The EPPI_CTL.CLKGATEN bit enables using the EPPI_FS3 pin as a clock gating pin. When EPPI_CTL.CLKGATEN is set, the EPPI_FS3 pin acts as a clock gating signal, and both the internal and external clock are gated. Note that the EPPI_FS3 pin gating signal is active low, and the EPPI_CTL.CLKGATEN selection is ignored if EPPI_CTL.MUXSEL is set or EPPI_CTL.FSCFG equals 0x3. |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                         | Disable                    |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                         | Enable                     |
| 30      | MUXSEL   | MUX Select.<br>The EPPI_CTL.MUXSEL bit enables multiplexing of a primary and alternate camera using the EPPI main data and clock lines. For more information on this feature, see the EPPI functional description.                                                                                                                                                                                        |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                         | Normal Operation           |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                         | Multiplexed Operation      |
| 29      | DMAFINEN | DMA Finish Enable.<br>The EPPI_CTL.DMAFINEN bit selects whether or not the EPPI sends a finish command (010) through the DDE COMMAND line soon after a frame/line is received completely.                                                                                                                                                                                                                 |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                         | No Finish Command          |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                         | Enable Send Finish Command |
| 28      | DMACFG   | One or Two DMA Channels Mode.<br>The EPPI_CTL.DMACFG bit is valid only if EPPI_CTL.SPLTE0 is set. If EPPI_CTL.DMACFG is set, the EPPI uses two DMA channels. And, if EPPI_CTL.DMACFG is cleared, the EPPI uses only one DMA channel.                                                                                                                                                                      |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                         | PPI uses one DMA Channel   |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                         | PPI uses two DMA Channels  |

| 8       | BLANKGEN | Blanking Generation (ITU Output Mode).<br>The EPPI_CTL.BLANKGEN enables ITU output with internal blanking. In GP 8, 10 transmit bit modes (when EPPI_CTL.SPLTWRD is cleared) and 16-, 20-, and 24-bit transmit modes (when EPPI_CTL.SPLTWRD is set), EPPI_CTL.BLANKGEN selects whether or not the EPPI generates blanking and generates preamble and insertion with active data from memory. |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                     |
| 7       | ITUTYPE  | ITU Interlace or Progressive.<br>The EPPI_CTL.ITUTYPE selects interlaced or progressive operation for ITU656 mode. This selection is valid for both TX and RX modes.                                                                                                                                                                                                                         |

## FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register

The EPPI\_FS1\_WLHB register's content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2 or 3 FS modes, EPPI\_FS1\_WLHB is used for the generation of Frame Sync 1. The register contains the width required for EPPI\_FS1 based on the EPPI\_CLK clock.

In GP transmit mode with EPPI\_CTL.BLANKGEN set, this register contains the number of samples of horizontal blanking per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for the EPPI\_FS1\_WLHB register is illegal. If programmed as 0, the EPPI regards the EPPI\_FS1\_WLHB as containing 1.

### EPPI\_FS1\_WLHB: FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register - R/W

Reset = 0x0000 0000

**Figure 31-24:** EPPI\_FS1\_WLHB Register Diagram

Table 31-60: EPPI\_FS1\_WLHB Register Fields

| Bit No. | Bit Name | Description/Enumeration                      |
|---------|----------|----------------------------------------------|
| 31:0    | VALUE    | Frame Sync Width or Blanking Samples Number. |

FS1 Period Register / EPPI Active Samples Per Line Register

The EPPI\_FS1\_PASPL register content varies depending on whether the EPPI is in GP1/2/3 FS modes or in GP transmit mode.

In GP 1, 2, or 3 FS modes, EPPI\_FS1\_PASPL is used for the generation of Frame Sync 1. The register contains the period required for EPPI\_FS1 based on the EPPI\_CLK clock.

In GP transmit mode with EPPI\_CTL.BLANKGEN set, this register contains the number of samples of active video or vertical blanking samples per line. When used for blanking generation, only the lower 16 bits are valid.

Note that a value of 0 for this register is illegal. If programmed as 0, the EPPI regards the EPPI\_FS1\_PASPL as containing 1.

EPPI\_FS1\_PASPL: FS1 Period Register / EPPI Active Samples Per Line Register - R/W

Reset = 0x0000 0000

Figure 31-25: EPPI\_FS1\_PASPL Register Diagram

| Bit No. | Bit Name | Description/Enumeration              |
|---------|----------|--------------------------------------|
| 31:0    | VALUE    | Frame Sync Period or Samples Number. |

## FS2 Width Register / EPPI Lines Of Vertical Blanking Register

The EPPI\_FS2\_WLVB register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, EPPI\_FS2\_WLVB is used for the generation of Frame Sync 2. The register contains the width required for EPPI\_FS2 based on the EPPI\_CLK clock.

In GP transmit mode with EPPI\_CTL.BLANKGEN set, this register contains the number or lines of vertical blanking.

Note that for progressive video, EPPI\_FS2\_WLVB.F2VBBD and EPPI\_FS2\_WLVB.F2VBAD are ignored.

**EPPI\_FS2\_WLVB: FS2 Width Register / EPPI Lines Of Vertical Blanking Register - R/W**

Reset = 0x0000 0000

**Figure 31-26:** EPPI\_FS2\_WLVB Register Diagram

**Table 31-62:** EPPI\_FS2\_WLVB Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                            |
|---------|----------|----------------------------------------------------------------------------------------------------|
| 31:24   | F2VBAD   | Field 2 Vertical Blanking After Data.<br>The number of lines of vertical blanking after field 2.   |

| 7:0     | F1VBBD   | Field 1 Vertical Blanking Before Data.<br>The number of lines of Vertical blanking before field 1. |

## FS2 Period Register / EPPI Active Lines Per Field Register

The EPPI\_FS2\_PALPF register content varies depending on whether the EPPI is in GP2/3 FS modes or in GP transmit mode.

In GP 2 or 3 FS modes, EPPI\_FS2\_PALPF is used for the generation of Frame Sync 2. This register contains the period required for EPPI\_FS2 based on the EPPI\_CLK clock.

In GP transmit mode with EPPI\_CTL.BLANKGEN set, this register contains the number of lines of active video per field.

Note that a value of 0 for EPPI\_FS2\_PALPF.F1ACT or EPPI\_FS2\_PALPF.F2ACT is illegal. If either is programmed as 0, the EPPI regard the 0 value fields as containing 1.

Also note that for progressive video, EPPI\_FS2\_PALPF.F2ACT is ignored.

EPPI\_FS2\_PALPF: FS2 Period Register / EPPI Active Lines Per Field Register - R/W

Reset = 0x0000 0000

## Interrupt Mask Register

The EPPI\_IMSK permits masking (if associated bit is set) of EPPI error interrupts for YFIFO underflow or overflow, CFIFO underflow or overflow, line track overflow error, line track underflow error, frame track overflow error, frame track underflow error, and ERR\_NCOR (ITU preamble error not corrected). These conditions are flagged in the EPPI\_STAT register and cleared by write-1-to-clear.

**EPPI\_IMSK: Interrupt Mask Register - R/W**

Reset = 0x0000 0000

**Figure 31-28:** EPPI\_IMSK Register Diagram

**Table 31-64:** EPPI\_IMSK Register Fields

| Bit No. | Bit Name  | Description/Enumeration                          |
|---------|-----------|--------------------------------------------------|
| 7       | PXPERR    | PxP Ready Error Interrupt Mask.                  |
|         |           | 0 Unmask Interrupt                               |

## Clipping Register for ODD (Chroma) Data

The `EPPI_ODDCLIP` register selects the clipping threshold for chroma data, which provides clipping of individual video components.

The high odd and low odd spaces in `EPPI_ODDCLIP` are 16-bits wide and (depending on the `EPPI_CTL.DLEN` selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits 25:16 constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with `EPPI_CTL.SPLTWRD` set, the luma data gets the clipping threshold levels of `EPPI_EVENCLIP`, and the chroma data gets the clipping threshold levels of `EPPI_ODDCLIP`.

Also note that the EPPI\_EVENCLIP and EPPI\_ODDCLIP registers are ignored when EPPI\_CTL.RGBFMTEN is set.

**EPPI\_ODDCLIP: Clipping Register for ODD (Chroma) Data - R/W**

Reset = 0xffff 0000

| Bit No. | Bit Name | Description/Enumeration                    |
|---------|----------|--------------------------------------------|
| 31:16   | HIGHODD  | High Odd Clipping Threshold (Chroma Data). |
| 15:0    | LOWODD   | Low Odd Clipping Threshold (Chroma Data).  |

## Clipping Register for EVEN (Luma) Data

The EPPI\_EVENCLIP register selects the clipping threshold for luma data, which provides clipping of individual video components.

The high even and low even spaces in EPPI\_EVENCLIP are 16-bits wide and (depending on the EPPI\_CTL.DLEN selection) only the corresponding video component bits are considered for clipping.

For example, if the EPPI is programmed in 10-bit mode, bits [9:0] and bits 25:16 constitute the clipping thresholds. The higher bits are (in this case) ignored.

Using the this method, 8-, 10-, 12- and 16-bit clipping thresholds can be set.

Note that when the EPPI is programmed in 16-, 20-, or 24-bit mode with EPPI\_CTL.SPLTWRD set, the luma data gets the clipping threshold levels of EPPI\_EVENCLIP, and the chroma data gets the clipping threshold levels of EPPI\_ODDCLIP.

Also note that the EPPI\_EVENCLIP and EPPI\_ODDCLIP registers are ignored when EPPI\_CTL.RGBFMTEN is set.

EPPI\_EVENCLIP: Clipping Register for EVEN (Luma) Data - R/W

Reset = 0xffff 0000

Figure 31-30: EPPI\_EVENCLIP Register Diagram

Table 31-66: EPPI\_EVENCLIP Register Fields

| 31:16   | HIGHEVEN | High Even Clipping Threshold (Luma Data). |
| 15:0    | LOWEVEN  | Low Even Clipping Threshold (Luma Data).  |

Frame Sync 1 Delay Value

The EPPI\_FS1\_DLY selects the delay count (based on the period of the EPPI\_CLK clock) between the first rising edge of EPPI\_CLK after EPPI enabled and the first active edge of the associated Frame Sync when the internal Frame Sync is used.

Note that if EPPI\_FS1\_DLY or EPPI\_FS2\_DLY are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

EPPI\_FS1\_DLY: Frame Sync 1 Delay Value - R/W

Reset = 0x0000 0000

**Table 31-67:** EPPI\_FS1\_DLY Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 31:0    | FS1_DLY  | Frame Sync 1 Delay Count. |

## Frame Sync 2 Delay Value

The EPPI\_FS2\_DLY selects the delay count (based on the period of the EPPI\_CLK clock) between the first rising edge of EPPI\_CLK after EPPI enabled and the first active edge of the associated Frame Sync when the internal Frame Sync is used.

Note that if EPPI\_FS1\_DLY or EPPI\_FS2\_DLY are programmed with value 0, the EPPI operates as though 0 value is 1, and the first frame sync transition occurs after the completion of one period value of the respective counters.

**EPPI\_FS2\_DLY: Frame Sync 2 Delay Value - R/W**

Reset = 0x0000 0000

## 32 Pixel Compositor (PIXC)

The pixel compositor (PIXC) provides data overlay, transparent color, and color space conversion support. This allows for supporting different video outputs including active (TFT) flat-panel digital color/monochrome LCD displays and analog NTSC/PAL. The color space conversion and text/graphic overlay capabilities, along with visual effect controls, such as transparency control, shorten the processing time on an image data stream, reduce power consumption and save system board space by removing the need for external glue logic.

The PIXC is used to combine and format the data streams required by a wide variety of digital LCD panels and NTSC/PAL analog encoders. It provides all the control needed to allow two data streams from two separate data buffers to be combined and converted into appropriate formats for both LCD panels and video output displays. The main image buffer provides the basic background image presented in the data stream. The overlay image buffer allows the user to add foreground text and graphics on top of the main image data stream. This feature is useful for printing additional graphical or textual information on the screen, such as symbols or a menu, while showing the main image in the background.

Overlay is an option and can be enabled or disabled. If it is disabled, the blender/compositor is bypassed and the data stream from the main image buffer goes directly to memory with optional color space conversion.

Transparent color is just a special case of blending, masking off the blend operation on a pixel-by-pixel basis. In other words, the overlay region consists of sub-regions in any particular color convenient to the programmer and then, if the color data for a given overlay pixel matches the specified transparent color, the overlay function is masked for that pixel and its data is taken solely from the main image buffer, which is stored in memory in either YUV 4:2:2 interleaved format or RGB888 format

Regardless of the data format or buffer structure, each color element is 8 bits wide. If overlay is enabled, a graphics/text overlay data buffer is defined in memory. The color space converter can switch positions among any of the three locations; it can be in the image data path, the overlay data path, or after the blender. The exact position of the color space converter depends on the input and output data formats.

Since the end display may be a TV (NTSC/PAL) or an LCD panel, and since the image/overlay input buffers may be in either RGB888 or YUV4:2:2 format, a color space conversion may be needed. The color space conversion is selected according to the input data stream format of the PIXC. A YUV-to-RGB format conversion is necessary if the end display is an LCD and if either of the PIXC input data streams is in YUV 4:2:2 format. Similarly, an RGB-to-YUV format conversion is necessary if the end display is a TV and if either of the PIXC input data streams is in RGB888 format.

If the final display device is an LCD, the output RGB data stream is always packed in RGB 8-bit serial format when transferring back to memory. Similarly, if the final display device is a TV, the YUV data stream is always packed in YUV 4:2:2 interleaved format when transferring back to memory.

## PIXC Features

PIXC features include:

- Hardware-based graphics and text overlays
- YUV 4:2:2, RGB888, RGB666 or RGB565 input data formats
- Programmable color space conversion on the main image or the overlay image data path
- Overlay content transparency ratio control
- Transparent color, specified in the desired color space (RGB or YUV)
- Two DMA input channels and one DMA output channel
- Interface to the pixel pipe

## PIXC Functional Description

The PIXC implements the following main functions.

- Graphics/text overlay (including video overlay for small frame sizes)
- Transparency control (alpha blending) of the overlay pixel data
- Transparent color (chroma keying) of the overlay stream
- Color space conversion for LCD panels or NTSC/PAL displays

## Color Space Converter Output Thresholds

Each PIXC output sample is 8 bits wide, whether it is an R, G, B, Y, U or V component value. Therefore, any output sample must be in the 0 to 255 range. Since all the coefficients are programmable, some of the inputs, when operated upon by the coefficients, may produce an output outside the 0 to 255 range. In such cases, the PIXC clips the output component's value to 0 or 255.

## YUV Conversion Modes

When the color space converter operates between two color spaces, it requires all components of each pixel to be present in the data stream.

Therefore, the PIXC internally up samples the YUV 4:2:2 data stream before a YUV-to-RGB conversion and similarly down samples the YUV 4:4:4 data stream after a RGB-to-YUV conversion. The re-sampling

always takes place between YUV 4:2:2 and YUV 4:4:4 formats, but a certain flexibility is provided with regard to how the re-sampling is done by the PIXC in each case.

- Up sampling

A YUV 4:2:2-to-YUV 4:4:4 conversion can be performed either by averaging or by duplicating the pixel components. The UDSMOD bit in the PIXC\_CTL register specifies the up sampling mode. The default setting of this bit is 0, which corresponds to duplication of the chroma components (Us and Vs) from the odd pixels to the even pixels:

|                       |                                     |
|-----------------------|-------------------------------------|
| YUV 4:2:2 input:      | V1Y1, U1Y2, V3Y3, U3Y4, ...         |
| YUV 4:4:4 conversion: | Y1U1V1, Y2U1V1, Y3U3V3, Y4U3V3, ... |

Setting the PIXC\_CTL.UDSMOD bit to 1 enables the averaging of the chroma components of the preceding and succeeding pixels to obtain the intermediate chroma value. In other words, two consecutive odd-numbered pixels' chroma components are averaged to obtain the intermediate even-numbered pixel's chroma components:

|                       |                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| YUV 4:2:2 input:      | V1Y1, U1Y2, V3Y3, U3Y4, ...                                                                                       |
| YUV 4:4:4 conversion: | Y1U1V1, Y2U2V2 [ $U2=(U1+U3)/2$ ,<br>$V2=(V1+V3)/2$ ], Y3U3V3, Y4U4V4<br>[ $U4=(U3+U5)/2$ , $V4=(V3+V5)/2$ ], ... |

If the sum of the preceding and succeeding pixels' U/V components is an odd number, the average is rounded down (truncated to an integer value).

Since the last pixel on a line is always an even-numbered pixel, the last odd pixel value on that line is used as the last even pixel value during up sampling.

- Down Sampling

A YUV 4:4:4-to-YUV 4:2:2 conversion can be performed either by averaging or by dropping the pixel components. The PIXC\_CTL.UDSMOD bit also governs the down sampling mode. Setting the PIXC\_CTL.UDSMOD bit to 0 (default) enables the dropping of the chroma components of the even numbered pixels:

|                       |                                     |
|-----------------------|-------------------------------------|
| YUV 4:4:4 input:      | Y1U1V1, Y2U2V2, Y3U3V3, Y4U4V4, ... |
| YUV 4:2:2 conversion: | V1Y1, U1Y2, V3Y3, U3Y4, ...         |

|                       |                                     |
|-----------------------|-------------------------------------|
| YUV 4:4:4 input:      | Y1U1V1, Y2U2V2, Y3U3V3, Y4U4V4, ... |
| YUV 4:2:2 conversion: | V12Y1, U12Y2, V34Y3, U34Y4, ...     |
|                       | $[U12=(U1+U2)/2, U34=(U3+U4)/2]$    |
|                       | $[V12=(V1+V2)/2, V34=(V3+V4)/2]$    |

## PIXC Actions

The table below lists the PIXC actions that take place based on any possible combination of image, overlay, and output data formats.

**Table 32-1:** PIXC Actions

| YUV | No Overlay | RGB | US followed by CSC                                      |
|-----|------------|-----|---------------------------------------------------------|
| RGB | No Overlay | YUV | CSC followed by DS                                      |
| YUV | YUV        | YUV | US in both paths followed by DS before output           |
| YUV | RGB        | RGB | US in image path, CSC in image path                     |
| YUV | YUV        | RGB | US in both paths, followed by CSC                       |
| YUV | RGB        | YUV | CSC in overlay path, US in image path, DS before output |
| RGB | YUV        | YUV | CSC in image path, US in overlay path, DS before output |
| RGB | YUV        | RGB | US in overlay path, CSC in overlay path                 |
| RGB | RGB        | YUV | CSC followed by DS                                      |
| RGB | RGB        | RGB | No CSC, No US, No DS                                    |

- CSC = Color Space Conversion
- US = Up sampling
- DS = Down Sampling
- YUV = YUV 4:2:2 format

- RGB = RGB888 format

## Recommendation

For best results, the overlay should start on an odd-numbered pixel so that the U and V components of the image and the overlay are aligned. Otherwise artifacts may occur in the combined image.

When both the image and the overlay are in YUV 4:2:2 format and the output is also in YUV 4:2:2 format, the duplicating-dropping mode (PIXC\_CTL.UDSMOD) is used to prevent a low-pass filtering effect on the images

## Special Use Cases

There are ways by which the PIXC can be made to operate on certain data formats that it does not support in any standard modes. For example, YUV 4:4:4 is similar to RGB 888 with respect to the number of pixels per 32-bit DMA word. So the PIXC can be configured to work with the YUV 4:4:4 data format by intelligently programming the IFRMT, OVFRMT, and OUTFRMT bit fields in the PIXC\_CTL register and the color space conversion coefficients.

These special usage cases are shown in the figures below.

### Example 1 - Currently Defined Mode

### Example 1 - Special Usage of this Mode

- IFRMT = YUV
- OVFRMT = YUV
- OUTFRMT = RGB

## Example 2 - Currently Defined Mode

## Example 2 - Special Usage of this Mode

In the special usage of this mode, YUV 4:4:4 input produces a blended YUV 4:2:2 or YUV 4:4:4 data stream. A CSC matrix with coefficients of 1 is needed.

### Example 3 - Currently Defined Mode

### Example 3 - Special Usage of this Mode

In the special usage of this mode, a YUV 4:4:4 input stream and a YUV 4:2:2 input stream can be blended to produce either a YUV 4:4:4 or a YUV 4:2:2 output stream.

### Example 4 - Currently Defined Mode

### Example 4 - Special Usage of this Mode

- PIXC\_EN = 1
- OVR\_A\_EN = 0
- OVR\_B\_EN = 0

- IMG\_FORM = RGB
- OUT\_FORM = YUV
- All CSC coefficients = 1

## PIXC Register List

The pixel compositor (PIXC) provides data overlay, transparent color, and color space conversion support for active (TFT) flat-panel digital color/monochrome LCD displays or analog NTSC/PAL video output. A set of registers govern PIXC operations. For more information on PIXC functionality, see the PIXC register descriptions. Programmers should avoid writing to any of the PIXC registers when the module is enabled. Writing to the PIXC registers during the module enabled state can lead to unpredictable behavior of the PIXC. All registers can be read when the PIXC is in the enabled state, and this does not cause any change of status in the PIXC, but register writes should happen only when the PIXC is disabled, or stalled by an interrupt condition.

**Table 32-2:** PIXC Module Registers

| Name          | Description                           |
|---------------|---------------------------------------|
| PIXC_CTL      | Control Register                      |
| PIXC_PPL      | Pixels Per Line Register              |
| PIXC_LPF      | Line Per Frame Register               |
| PIXC_HSTART_A | Overlay A Horizontal Start Register   |
| PIXC_HEND_A   | Overlay A Horizontal End Register     |
| PIXC_VSTART_A | Overlay A Vertical Start Register     |
| PIXC_VEND_A   | Overlay A Vertical End Register       |
| PIXC_TRANSP_A | Overlay A Transparency Ratio Register |
| PIXC_HSTART_B | Overlay B Horizontal Start Register   |
| PIXC_HEND_B   | Overlay B Horizontal End Register     |

**Table 32-2:** PIXC Module Registers (Continued)

| Name          | Description                           |
|---------------|---------------------------------------|
| PIXC_VSTART_B | Overlay B Vertical Start Register     |
| PIXC_VEND_B   | Overlay B Vertical End Register       |
| PIXC_TRANSP_B | Overlay B Transparency Ratio Register |
| PIXC_IRQSTAT  | Interrupt Status Register             |
| PIXC_CONRY    | RY Conversion Component Register      |
| PIXC_CONGU    | GU Conversion Component Register      |
| PIXC_CONBV    | BV Conversion Component Register      |
| PIXC_CCBIAS   | Conversion Bias Register              |
| PIXC_TC       | Transparency Color Register           |
| PIXC_REVID    | Revision Id                           |

## ADSP-BF60x PIXC Interrupt List

**Table 32-3:** ADSP-BF60x PIXC Interrupt List

| Description         | ID  | DMA Channel | Sensitivity |
|---------------------|-----|-------------|-------------|
| PIXC0 Channel 0 DMA | 107 | 35          | LEVEL       |
| PIXC0 Channel 1 DMA | 108 | 36          | LEVEL       |
| PIXC0 Channel 2 DMA | 109 | 37          | LEVEL       |
| PIXC0 Status        | 110 |             | LEVEL       |

## ADSP-BF60x PIXC Trigger List

**Table 32-4:** Masters ADSP-BF60x PIXC Trigger List

| Description         | ID | Sensitivity |
|---------------------|----|-------------|
| PIXC0 Channel 0 DMA | 57 | PULSE/EDGE  |
| PIXC0 Channel 1 DMA | 58 | PULSE/EDGE  |
| PIXC0 Channel 2 DMA | 59 | PULSE/EDGE  |
|                     |    |             |

**Table 32-5:** Slaves ADSP-BF60x PIXC Trigger List

| Description         | ID | Sensitivity |
|---------------------|----|-------------|
| PIXC0 Channel 0 DMA | 57 |             |
| PIXC0 Channel 1 DMA | 58 |             |
| PIXC0 Channel 2 DMA | 59 |             |
|                     |    |             |

## PIXC Definitions

To make the best use of the PIXC, it is useful to understand the following terms.

### NTSC/PAL

The two most common video standards used. NTSC is the video system or standard used in North America and most of South America. In NTSC, 30 frames are transmitted each second. Each frame is made

up of 525 individual scan lines. PAL is the predominant video system or standard mostly used overseas. In PAL, 25 frames are transmitted each second. Each frame is made up of 625 individual scan lines.

### RGB888 format

RGB is a color space where pixels are defined by three color values; one red (R), one green (G) and one blue (B). The suffix signifies the bit widths for these color components. In this case, RGB888 means that each red, green and blue value is 8-bits each.

### YUV 4:2:2 interleaved format

YUV is a color space where pixels are defined by a luminance (Y) component and chrominance (UV) components. The suffix signifies how the chrominance components have been decimated as well as formatting. In this case, the YUV422 format has the chrominance decimated by two, meaning only half of each chrominance component are available. Typical YUV422 formatting interleaves the luminance and chrominance such as U1Y1V1Y2U2Y3V2Y4.

### Data Overlay

Process of blending or replacing a pixel from an image with another pixel.

## PIXC Block Diagram

A top-level micro architecture diagram of the PIXC appears in the following figure. As shown in the figure, the PIXC uses three DMA channels: one for the image data, one for the overlay data and one for storing the results back to memory. Frame C (output frame) can also be fed back to the PIXC for multiple stages of processing, taking the place of frame A (main input image) when this happens. The main input image and output frame can alternatively be piped from or to another peripheral via the Video Subsystem, respectively.

**Figure 32-1:** Pixel Compositor Top-Level Diagram

**Figure 32-2:** PIXC Functional Block Diagram

## PIXC Architectural Concepts

The PIXC data interface can be configured to obtain the input main image from memory via DMA or piped from a different peripheral configured by the Video Subsystem. The output result image can also be sent back to memory via DMA or piped to a peripheral. Also, the output can be fed back into the PIXC for multiple stages of processing. The overlay image data must be brought in from memory via DMA.

### Pixel Pipe (PxP) Interface

The PIXC supports a pixel pipe (PxP) interface at the input as well as the output sides. The input side is multiplexed with the DMA channel carrying the input image data from memory. The video subsystem connectivity determines whether the PIXC image data source is connected to the IFIFO or the Pixel Pipe. The output composite image/color converted image can be either transferred to memory via DMA or to the PVP/EPPI via the PxP. This is also determined by the video subsystem connectivity.

If the PIXC image input is programmed to connect to the PxP bus then:

1. The PIXC expects only complete frames from the PxP. Each line should contain the exact number of pixels as programmed in the `PIXC_PPL` register and each frame should contain as many lines as programmed in the `PIXC_LPF` register. The EPPI is the only source of data when the PIXC input connects to the PxP. It is ensured by the EPPI that once a frame starts, no further frame sync is passed on the PxP bus until the frame is completed.
2. Internal signaling is used to start the pixel processing in the PIXC. The PPL counter increments at pixel valid. The LPF counter is incremented only when the PPL counter rolls over and resets to one when the max LPF count is reached (as programmed in the `PIXC_LPF` register).

#### PIXC Start Synchronization in PxP Input Mode

When the PIXC is enabled after configuring it to take the image data from the PxP bus, the PIXC internal logic synchronizes itself to the incoming PxP frame sync. The PIXC ignores all the incoming data until it gets this PxP frame sync from the input PxP bus. After the internal frame sync is recognized by the PIXC, its engine starts processing the incoming data. This removes any restriction of the relative enable times of the PIXC and the EPPI. Either could be enabled first. If the EPPI is enabled first and the PIXC is enabled later, the PIXC would start its frame processing only at the start of the next frame after PIXC is enabled.

## DMA Interface

The PIXC has a native DMA controller with three channels. Two are used for the input; one for transferring the input image to the PIXC from memory and one for transferring the overlay image to the PIXC from memory. One channel is used for the output, transferring the blended data to memory.

The two input DMA channels with 32-bit bus widths take the image data and overlay graphics/text data from their buffers into two separate FIFO's where the data is then unpacked. Each of these FIFO buffers is 32 bits wide and contains 8 entries.

In the blender, (8-bit) pixel elements from two buffers are mixed together. One dedicated DMA channel transfers the combined pixel data back to memory. Each channel is a DDE instance. A local arbiter arbitrates between the three channels. This arbitrated request will be forwarded to the system crossbar. The PIXC only has one connection to the system crossbar.

When using the DMA to interface to the PIXC, at least two DMA channels should be enabled and configured appropriately; The image DMA channel and the output DMA channel. Furthermore, when the overlay function of PIXC is enabled, the overlay DMA channel should be enabled and configured as well.

## PIXC Data Overlay

Overlay is an optional function, so it can be enabled or disabled. If it is disabled, all overlay functionality is bypassed, and a single data stream from the main image data buffer goes directly to the image output buffer, after an optional format conversion. If it is enabled, the blender combines the pixel data from the two image input buffers.

The overlay image is located in a user-defined rectangle within the main image and, in most cases, the overlay image is smaller than the main image. The figure below illustrates an example of the main and overlay image regions on a screen, where a foreground triangle overlay sits on top of the main image in the background. Although the figure does not show this explicitly, (H-Start, V-Start) can equal (0,0).

**Figure 32-3:** Main Image and Overlay Image Region

In certain situations, it may be beneficial to only DMA the region of the main image that is affected by the overlay instead of bringing in the entire main image. For example, in a situation where the intent is to overlay an image over the main image and to store the result back over the main image, one could setup a 2D-DMA to only bring in the area of the main image that is affected by the overlay. This may reduce the amount of DMA activity thus potentially improving system performance.

There is a set of an additional registers that can be used to specify a second overlay region, so that two separate overlay blocks can be defined simultaneously. Furthermore, either or both of these overlay coordinate register sets can be enabled or disabled at one time, since separate enable bits in the PIXC\_CTL register (OVAEN and OVBEN) exist in the PIXC control register for each of the overlay register sets.

If there are more than two overlay blocks needed in a given application, the two sets of overlay registers must be managed by the user to perform the additional overlays. This can be done using an interrupt service routine, where the interrupt from the PIXC is used to re-program the overlay coordinate registers.

The PIXC can generate an interrupt under two conditions: at the end of the last valid overlay and at the end of a frame.

Either of these interrupts can be enabled or disabled. However, the PIXC only has one interrupt line output, so it raises an interrupt (under the appropriate condition) when either of these two interrupts is triggered. If both interrupts are enabled, the interrupt status register of the PIXC indicates which of the two conditions caused the interrupt to occur. Once the PIXC generates an interrupt, it stalls the pixel processing until software (ISR) clears the interrupt. However, the FIFOs do not stall and keep filling up even when the PIXC is in a stalled state. Both interrupts can be cleared by writing a 1 to the respective interrupt status bits.

After each interrupt (whether it is a last-valid-overlay interrupt or an end-of-frame interrupt), the PIXC restarts processing with coordinate register set A. In other words, at the time of clearing the interrupt:

- If coordinate set A is enabled (`PIXC_CTL.OVAEN = 1`), the PIXC assumes that the first incoming data over the bus is to be overlaid on the area specified in coordinate set A.
- If coordinate set A is disabled (`PIXC_CTL.OVAEN = 0`), and coordinate set B is enabled (`PIXC_CTL.OVBEN = 1`), the PIXC assumes that the first incoming data over the data bus is to be overlaid on the area specified in coordinate set B.
- If both coordinate sets are disabled, the PIXC flushes the overlay FIFO and make no more data requests on the overlay DMA channel.

**NOTE:** The overlay enable bits `PIXC_CTL.OVAEN` and `PIXC_CTL.OVBEN` should only be changed inside the interrupt service routines of the PIXC interrupts, or when the overlay block is disabled.

Note that the module enable bit (`PIXC_CTL.EN`) is the root enable for the PIXC. Both the `OVAEN` and `OVBEN` bits in the `PIXC_CTL` register are gated with `PIXC_CTL.EN` bit, so if `PIXC_CTL.EN = 0`, the individual overlay enable bits have no effect, and the module remains disabled. When `PIXC_CTL.EN = 0`, both the image and overlay FIFOs are flushed and no more DMA requests are made on either of the DMA channels.

Once the DMAs are enabled, the PIXC keeps track of the current pixel being displayed from the main image data by reading from two user-programmable registers: `PIXC_PPL`, which stores the number of pixels per line, and `PIXC_LPF`, which stores the number of lines per frame of the display device.

When the pixel count reaches the top left corner (H-Start, V-Start) of overlay data, the PIXC starts the overlay. When the pixel count reaches the top right corner (H-End, V-Start) of overlay data, the PIXC stops the overlay. It starts again at the next line at (H-Start, V-Start+1) and stop at (H-End, V-Start + 1), and so on until the entire overlay frame is processed.

**NOTE:** Internally, the start of the overlay DMA would have been preempted by the PIXC before the actual processing of the first overlay pixel, and DMA data would have been requested until the overlay FIFO were full. Similarly, the overlay DMA does not stop at the end of a line. The overlay FIFO continues to be filled with DMA data, even when the current pixel is not an overlay pixel, but the supply of overlay pixels from the overlay FIFO is simply halted.

The PIXC decides whether or not to perform overlay mixing for the current pixel by using the various PIXC register values. Therefore:

- The `PIXC_PPL` and `PIXC_LPF` must be programmed correctly (and cannot be 0).
- The `HSTART` and `HEND` must be less than or equal to `PIXC_PPL`.
- The `VSTART` and `VEND` must be less than or equal to `PIXC_LPF`.

The user can define multiple rectangular regions covering several separate overlays, using the same number of DMA descriptors, where each DMA descriptor corresponds to an overlay region.

Multiple overlay regions are split into two cases:

- Overlay regions with no horizontal overlap – Here software can maintain separate areas in memory for both overlay regions, with separate H-Start, V-Start, H-End, and V-End coordinates for each region. After the first overlay is completed, the DMA chain pointer can load the next overlay parameters (index, count, and modifier) to the DMA registers of the corresponding DMA channel.

**Figure 32-4:** Overlay Regions With No Horizontal Overlap

- Overlay regions with horizontal overlap – In these cases software has to maintain a combined overlay region in memory. This includes some in-between area where there is no overlay. This region of memory has to be filled with the transparent color value (explained below). The H-Start, V-Start, H-End and V-End coordinates contain the values of the combined overlay region.

**Figure 32-5:** Overlay Regions With Horizontal Overlap

## PIXC Transparency Control

When the overlay function is enabled, each overlay pixel is combined with each main image pixel to generate the displayed output pixel to be displayed. Each pixel combination is controlled by a transparency

ratio value alpha ( $\alpha$ ), a 4-bit value that determines the proportion of overlay and main image that contribute to the output pixel. The pixel combination algorithm can be expressed as:

$$C = \frac{B(\alpha + 1)}{16} + \frac{A(15 - \alpha)}{16}$$

The table lists the multiplying factors for various  $\alpha$  values.

- A = 8-bit pixel data in main frame buffer (“background”)
- B = 8-bit pixel data in overlay buffer (“foreground”)
- C = 8-bit combined pixel data
- $\alpha$  = Transparency ratio code, which is a 4-bit value present in a memory-mapped register

**Table 32-6:** Multiplying Factors for Various  $\alpha$  Values

| $\alpha$ | Overlay Multiplying Factor | Image Multiplying Factor |
|----------|----------------------------|--------------------------|
| 0        | 1/16                       | 15/16                    |
| 1        | 2/16                       | 14/16                    |
| 2        | 3/16                       | 13/16                    |
| 3        | 4/16                       | 12/16                    |
| 4        | 5/16                       | 11/16                    |
| 5        | 6/16                       | 10/16                    |
| 6        | 7/16                       | 9/16                     |
| 7        | 8/16                       | 8/16                     |
| 8        | 9/16                       | 7/16                     |
| 9        | 10/16                      | 6/16                     |
| 10       | 11/16                      | 5/16                     |
| 11       | 12/16                      | 4/16                     |
| 12       | 13/16                      | 3/16                     |
| 13       | 14/16                      | 2/16                     |

**NOTE:** Passing the image alone can be achieved by disabling the overlay function.

Rounding is performed at the output of the blender, which rounds the combined pixel data to the nearest integer value.

## PIXC Transparency Color

A transparent color is a specific color that is removed from one image to reveal another “behind” it. This technique is also referred to as chroma keying. The principal subject is photographed or filmed against a background having a single color, usually in the blue or green spectrum. When the phase of the chroma signal corresponds to the pre-programmed state associated with the background color(s) behind the principal subject, the signal from the alternate background (which in this case comes from the main image channel) is inserted in the composite signal and presented at the output. When the phase of the chroma signal deviates from that associated with the background color(s) behind the principal subject, the picture data associated with the principal subject (in this case, the overlay image) is presented at the output. The figure below illustrates this concept.

**Figure 32-6:** Transparent Color (Chroma Keying)

In order to display the main image in the two triangle areas  $\triangle ABE$  and  $\triangle CDE$  in overlay block ABCD, the data in the overlay buffer corresponding to the pixels in the triangle areas  $\triangle ABE$  and  $\triangle CDE$  must hold a specific value, called the transparent color.

The PIXC provides a 24-bit MMR (storing three 8-bit color components) for each of the two overlay blocks to designate a particular RGB or YUV value as the transparent color. The transparent color must be in the same format (YUV 4:2:2 or RGB888) as the overlay data, regardless of whether or not a color space conversion is present in the overlay data path. The PIXC then compares each input pixel value on the overlay channel with this transparent color. If there is a match, the overlay pixel at this location is ignored by the blender, and the main image pixel at that location is assigned 100% weight.

**NOTE:** If YUV 4:2:2 is the overlay channel input data format, artifacts may occur at the edge of the transparent color region. In this case, it is preferable to set the `PIXC_CLT.UDSMOD` bit to 0 (duplicating-dropping mode), in order to get better control of the U and V components at the edge of the transparent color region.

## PIXC Color Space Conversion

Depending on the input data format and display device used, there may be a color space conversion performed on the data stream of the PIXC. If the input data is in YUV format, a YUV-to-RGB conversion can be performed for output to an LCD panel. If the input data is in RGB format, a RGB-to-YUV conversion can be performed for output to NTSC/PAL displays. The color space conversion may happen on any of the three paths (for example, the main image data path, the overlay image data path, or the combined data path). Register bits are used to specify the input, overlay and output formats. The color space converter block controls a number of cases of operation:

- Both the image and the overlay data are in the same format.
- The image and the overlay data are in different formats.
- Color space conversion only

Each case is described below, along with several special usage cases. Note that various scenarios may be shown in the same figure based on the output device chosen, though only a single output destination is supported at one time.

### Case 1 - Image and Overlay in the Same Format

Both input data streams (main image and overlay) are in the same format, either YUV 4:2:2 or RGB888, so a color space conversion may be performed after alpha blending, depending on the output type.

**Figure 32-7:** Image and Overlay in the Same Format

## Case 2 - Image and Overlay in Different Formats

In this case, the two input data streams are not in the same format. The PIXC has to perform a color space conversion on either the main input stream or the overlay input stream (depending on the required output format) before alpha blending can take place.

**Figure 32-8:** Image and Overlay in Different Formats

## Case 3 - Color Space Conversion Only

In this case, there is no overlay blending. The main image is brought into the PIXC, the color space converted, and then sent back to memory.

**Figure 32-9:** Color Space Conversion Only

For this mode, the register settings are: `PIXC_CTL.EN = 1`, `PIXC_CTL.OVAEN = 0` and `PIXC_CTL.OVBEN = 0`.

## PIXC Operating Modes

The color space converter block provides conversion operations in the following situations.

- When both the image and the overlay data are in the same format.
- When the image and the overlay data are in different formats.
- For color space conversion only

These situations are described in detail in the following sections. Note that various scenarios may be shown in the same figure based on the output device chosen, though only a single output destination is supported at one time.

### PIXC Mode Case 1 - Image/Overlay in the Same Format

Both input data streams (main image and overlay) are in the same format, either YUV 4:2:2 or RGB888, so a color space conversion may be performed after alpha blending, depending on the output type. See figures below.

**Figure 32-10:** Image and Overlay in the Same Format

## PIXC Mode Case 2 - Image/Overlay in Different Formats

In this case, the two input data streams are not in the same format. The PIXC has to perform a color space conversion on either the main input stream or the overlay input stream (depending on the required output format) before alpha blending can take place. See figures below.

**Figure 32-11:** Image and Overlay in Different Formats

## PIXC Mode Case 3 - Color Space Conversion Only

In this case, there is no overlay blending. The main image is brought into the PIXC, the color space converted, and then sent back to memory. See figures below.

**Figure 32-12:** Color Space Conversion Only

For this mode, the register settings are: PIXC\_CTL.EN = 1, PIXC\_CTL.OVAEN = 0 and PIXC\_CTL.OVBEN = 0.

## PIXC Image/Overlay/Format Actions

The table below lists the PIXC actions that take place based on any possible combination of image, overlay, and output data formats. Note the following definitions used in the table.

- CSC = Color Space Conversion
- US = Up sampling
- DS = Down Sampling
- YUV = YUV 4:2:2 format
- RGB = RGB888 format

**Table 32-7:** PIXC Actions

| Image Data Format | Overlay Data Format | Output Data Format | PIXC Actions                                            |
|-------------------|---------------------|--------------------|---------------------------------------------------------|
| YUV               | No Overlay          | RGB                | US followed by CSC                                      |
| RGB               | No Overlay          | YUV                | CSC followed by DS                                      |
| YUV               | YUV                 | YUV                | US in both paths followed by DS before output           |
| YUV               | RGB                 | RGB                | US in image path, CSC in image path                     |
| YUV               | YUV                 | RGB                | US in both paths, followed by CSC                       |
| YUV               | RGB                 | YUV                | CSC in overlay path, US in image path, DS before output |
| RGB               | YUV                 | YUV                | CSC in image path, US in overlay path, DS before output |
| RGB               | YUV                 | RGB                | US in overlay path, CSC in overlay path                 |
| RGB               | RGB                 | YUV                | CSC followed by DS                                      |
| RGB               | RGB                 | RGB                | No CSC, No US, No DS                                    |

## PIXC Image/Overlay/Format Recommendations

For best results, the overlay should start on an odd-numbered pixel so that the U and V components of the image and the overlay are aligned. Otherwise artifacts may occur in the combined image.

When both the image and the overlay are in YUV 4:2:2 format and the output is also in YUV 4:2:2 format, the duplicating-dropping mode (`PIXC_CTL.UDSMOD`) is used to prevent a low-pass filtering effect on the images

## PIXC Image/Overlay/Format Special Use Cases

There are ways by which the PIXC can be made to operate on certain data formats that it does not support in any standard modes. For example, YUV 4:4:4 is similar to RGB 888 with respect to the number of pixels per 32-bit DMA word. So the PIXC can be configured to work with the YUV 4:4:4 data format by intelligently programming the `IFRMT`, `OVRMT`, and `OUTFRMT` bit fields in the `PIXC_CTL` register and the color space conversion coefficients.

These special usage cases are shown in the sections that follow.

### Example 1 - YUV 4:2:2 to YUV 4:4:4 or LCD/RGB

See the figures for special use of this mode:

- `IFRMT` = YUV
- `OVRMT` = YUV
- `OUTFRMT` = RGB

**Figure 32-13:** YUV 4:2:2/YUV 4:2:2 to YUV 4:2:2 or LCD/RGB

**Figure 32-14:** YUV 4:2:2/YUV 4:2:2 to YUV 4:2:2 or YUV 4:4:4

## Example 2 - YUV 4:4:4 to YUV 4:4:4 or YUV 4:2:2

See the figures for special use of this mode.

In the special usage of this mode, YUV 4:4:4 input produces a blended YUV 4:2:2 or YUV 4:4:4 data stream. A CSC matrix with coefficients of 1 is needed.

**Figure 32-15:** RGB/RGB to LCD/RGB or YUV 4:2:2

**Figure 32-16:** YUV 4:4:4/YUV 4:4:4 to YUV 4:4:4 or YUV 4:2:2

## Example 3 - YUV 4:2:2/4:4:4 to YUV 4:4:4 or YUV 4:2:2

See the figures for special use of this mode.

In the special usage of this mode, a YUV 4:4:4 input stream and a YUV 4:2:2 input stream can be blended to produce either a YUV 4:4:4 or a YUV 4:2:2 output stream.

**Figure 32-17:** YUV 4:2:2/RGB to LCD/RGB or YUV 4:2:2

**Figure 32-18:** YUV 4:2:2 / YUV 4:4:4 to YUV 4:4:4 or YUV 4:2:2

### Example 4 - YUV 4:4:4 to YUV 4:2:2

See the figures for special use of this mode:

- PIXC\_EN = 1
- OVR\_A\_EN = 0
- OVR\_B\_EN = 0
- IMG\_FORM = RGB
- OUT\_FORM = YUV
- All CSC coefficients = 1

**Figure 32-19:** RGB to YUV 4:2:2

Figure 32-20: YUV 4:4:4 to YUV 4:2:2

## Color Space Conversion Matrix Equations

The PIXC color space conversion block implements the following matrix equation.

$$K \times \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix} \begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} + \begin{bmatrix} A_{14} \\ A_{24} \\ A_{34} \end{bmatrix} = \begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix}$$

The  $A_{xx}$  coefficients are 10-bit signed values represented in two's complement format.  $A_{11} \dots A_{33}$  are coefficient multipliers (for most cases, it is sufficient to specify these as integers between  $-512$  and  $511$ ), and  $A_{14}$ ,  $A_{24}$ ,  $A_{34}$  are simply offsets added to the result for each row.  $B_1$ ,  $B_2$ ,  $B_3$  represent the input pixel component values (for example, YUV or RGB) and  $C_1$ ,  $C_2$ ,  $C_3$  are the output pixel component values. Output pixel values are rounded to the nearest integer.

The constant  $K$  equals  $1/512$ . For example, to set  $A_{11}$ 's effective value to  $0.299$ , this coefficient's MMR should be programmed to  $\text{ROUND}(.299 \times 512)$ , or  $153$ . If a coefficient needs to be programmed with a value greater than  $1$ , an extra bit exists in each coefficient's MMR to specify if an extra multiply by  $4$  must be performed after multiplying the input value by its coefficient. However, this setting can only be specified for an entire row, so if this bit is set, all the coefficients for that row ( $A_{x1} - A_{x3}$ ) should be calculated as  $\text{ROUND}(\text{coeff} \times 512/4)$ . In other words, the constant  $K$  effectively becomes  $1/128$  for that row.

For reference, the matrix equations representing conversion between YUV and RGB formats are:

$$\begin{bmatrix} Y \\ U \\ V \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ -0.168 & -0.330 & 0.498 \\ 0.498 & -0.417 & -0.081 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 1.000 & 0.000 & 1.397 \\ 1.000 & -0.343 & -0.711 \\ 1.000 & 1.765 & 0.000 \end{bmatrix} \begin{bmatrix} Y \\ U \\ V \end{bmatrix} + \begin{bmatrix} -179 \\ 135 \\ -226 \end{bmatrix}$$

**NOTE:** For YUV-to-RGB conversion, the PIXC expects the input data to be arranged in the following order: VYUY, VYUY, and so on. As a result, if the input data is instead arranged as UYVY, UYVY, and so on, then, the columns  $A_{x2}$  and  $A_{x3}$  of the coefficient matrix are swapped.

For RGB-to-YUV conversion, the PIXC arranges the output data by default in the following order: VYUY, VYUY, and so on. If the output data is desired to instead be arranged as UYVY, UYVY, and so on, then, rows A2x and A3x of the coefficient and bias matrices are swapped.

## Color Space Converter Output Thresholds

Each PIXC output sample is 8 bits wide, whether it is an R, G, B, Y, U or V component value. Therefore, any output sample must be in the 0 to 255 range. Since all the coefficients are programmable, some of the inputs, when operated upon by the coefficients, may produce an output outside the 0 to 255 range. In such cases, the PIXC clips the output component's value to 0 or 255.

## YUV Re-Sampling

When the color space converter operates between two color spaces, it requires all components of each pixel to be present in the data stream.

Therefore, the PIXC internally up samples the YUV 4:2:2 data stream before a YUV-to-RGB conversion and similarly down samples the YUV 4:4:4 data stream after a RGB-to-YUV conversion. The re-sampling always takes place between YUV 4:2:2 and YUV 4:4:4 formats, but a certain flexibility is provided with regard to how the re-sampling is done by the PIXC in each case.

## Up Sampling

A YUV 4:2:2-to-YUV 4:4:4 conversion can be performed either by averaging or by duplicating the pixel components. The UDSDMOD bit in the PIXC\_CTL register specifies the up sampling mode. The default setting of this bit is 0, which corresponds to duplication of the chroma components (Us and Vs) from the odd pixels to the even pixels:

|                       |                                     |
|-----------------------|-------------------------------------|
| YUV 4:2:2 input:      | V1Y1, U1Y2, V3Y3, U3Y4, ...         |
| YUV 4:4:4 conversion: | Y1U1V1, Y2U1V1, Y3U3V3, Y4U3V3, ... |

Setting the PIXC\_CTL.UDSDMOD bit to 1 enables the averaging of the chroma components of the preceding and succeeding pixels to obtain the intermediate chroma value. In other words, two consecutive odd-numbered pixels' chroma components are averaged to obtain the intermediate even-numbered pixel's chroma components:

|                       |                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| YUV 4:2:2 input:      | V1Y1, U1Y2, V3Y3, U3Y4, ...                                                                                       |
| YUV 4:4:4 conversion: | Y1U1V1, Y2U2V2 [ $U2=(U1+U3)/2$ ,<br>$V2=(V1+V3)/2$ ], Y3U3V3, Y4U4V4<br>[ $U4=(U3+U5)/2$ , $V4=(V3+V5)/2$ ], ... |

If the sum of the preceding and succeeding pixels' U/V components is an odd number, the average is rounded down (truncated to an integer value).

Since the last pixel on a line is always an even-numbered pixel, the last odd pixel value on that line is used as the last even pixel value during up sampling.

## Down Sampling

A YUV 4:4:4-to-YUV 4:2:2 conversion can be performed either by averaging or by dropping the pixel components. The `PIXC_CTL.UDSMOD` bit also governs the down sampling mode. Setting the `PIXC_CTL.UDSMOD` bit to 0 (default) enables the dropping of the chroma components of the even numbered pixels.

|                       |                                     |
|-----------------------|-------------------------------------|
| YUV 4:4:4 input:      | Y1U1V1, Y2U2V2, Y3U3V3, Y4U4V4, ... |
| YUV 4:2:2 conversion: | V1Y1, U1Y2, V3Y3, U3Y4, ...         |

Setting the `PIXC_CTL.UDSMOD` bit to 1 enables the averaging of the chroma components of two consecutive pixels to obtain a single chroma value for a pixel pair.

## PIXC Supported Data Formats

For the implementation of overlay, the PIXC needs two input data streams from two separate data buffers; a main image buffer and an overlay buffer. The data in the main image buffer can be formatted as YUV 4:2:2, RGB888, RGB666 or RGB565 while the overlay data must be in YUV 4:2:2 or RGB888 format. The main image data and the overlay data can be in different formats. The output data can also be formatted at YUV 4:2:2, RGB888, RGB666 or RGB565.

## Operation in YUV 4:2:2 Format

Each Y/U/V component is stored in 8 bits of data. The PIXC only accepts a YUV 4:2:2 interleaved format, in the following sequence:

V1, Y1, U1, Y2, V3, Y3, U3, Y4 ...

(Two components with the same suffix number (for example, V1 and U1) implies that they are extracted from the same pixel.)

It is the user's responsibility to ensure that the YUV source data to the PIXC is in the correct interleaved format. Therefore, data processing may be necessary in order to meet this requirement.

The figures below illustrate correct PIXC input buffer structure and data stream format.

YUV 4:2:2 Data in an Interleaved Data Buffer Structure

|                          |        |        |        |        |  |          |          |
|--------------------------|--------|--------|--------|--------|--|----------|----------|
| ADDR_BASE + 0            | V1 1   | Y1 1   | U1 1   | Y1 2   |  | U1 639   | Y1 640   |
| ADDR_BASE + 1280         | V2 1   | Y2 1   | U2 1   | Y2 2   |  | U2 639   | Y2 640   |
|                          |        |        |        |        |  |          |          |
|                          |        |        |        |        |  |          |          |
| ADDR_BASE + (479 x 1280) | V480 1 | Y480 1 | U480 1 | Y480 2 |  | U480 639 | Y480 640 |

YUV 4:2:2 Expected Data Stream Format to PIXC

| B31 | B16 | B15 | B0  |
|-----|-----|-----|-----|
| Y2  | U1  | Y1  | V1  |
| Y4  | U3  | Y3  | V3  |
| ... | ... | ... | ... |
| ... | ... | ... | ... |

**Figure 32-21:** YUV 4:2:2 Expected Buffer Structure and Data Stream Format

The number of pixels per line in YUV mode must be an even number (for both input buffers), and the first chroma component in each line must be a V component.

## Operation in RGB888 Format

Each R/G/B component is stored in 8 bits of data. The figures below illustrate correct PIXC input buffer structure and data stream format.

RGB888 Data Expected Data Buffer Structure

|                          |        |      |      |      |  |          |          |
|--------------------------|--------|------|------|------|--|----------|----------|
| ADDR_BASE + 0            | R1 1   | G1 1 | B1 1 | R1 2 |  | G1 640   | B1 640   |
| ADDR_BASE + 1280         | R2 1   | R2 1 | B2 1 | B2 2 |  | G2 640   | B2 640   |
|                          |        |      |      |      |  |          |          |
|                          |        |      |      |      |  |          |          |
| ADDR_BASE + (479 x 1280) | R480 1 |      |      |      |  | U480 639 | Y480 640 |

RGB888 Expected Data Stream Format to PIXC

| B31 | B16 | B15 | B0  |
|-----|-----|-----|-----|
| R12 | B11 | G11 | R11 |
| G13 | R13 | B12 | G12 |
| ... | ... | ... | ... |
| ... | ... | ... | ... |

**Figure 32-22:** RGB888 Expected Buffer Structure and Data Stream Format

For operation in RGB format, the total number of pixels in both input buffers must be a multiple of 4, so that the image boundary aligns with a 32-bit DMA word boundary.

## Operation in RGB565 Format

Two pixels are packed into one 32 bit word. Each pixel occupies 16 bits. The figures below illustrates how the pixel data is arranged in memory.

**Figure 32-23:** Memory Arrangement – RGB565 Format

## Operation in RGB666 Format

Four pixels are packed into three 32 bit words. Each pixel occupies 24 bits. Of these 24 bits, the lowest 18 bits are the pixel data and the highest 6 bits are discarded for inputs and zeroed for outputs. The figure

below illustrates how the pixel data is arranged in memory. Note that 1 = pixel 1, 2 = pixel 2, 3 = pixel 3, and 4 = pixel 4.

**Figure 32-24:** Memory Arrangement – RGB666 Format

## Operation with RGB656 and RGB666 Formats

For RGB656 and RGB666 formats, the PIXC internal engine reads the relevant bits from the input and zero pads to 8 bits. The internal PIXC data path is always 8 bits. After the data path operations (mixer, color space conversion), if the output requires the pixels in either RGB565 or RGB666, the individual color components are truncated (the lower bits dropped) and converted to the required formats.

## PIXC Interrupt Signals

There are three DDE's associated with the PIXC. There is one for the input data, one for the input overlay frame and one for the output frame. The interrupts generated are due to the configuration of the DDE. For instance, the DMA channel that puts the results back to memory can be configured to generate an interrupt after every frame is completed. For more information, refer to the DDE section of the manual.

**Table 32-8:** Interrupt List for the PIXC Module

| Trigger | ID  | Module | Count | Type  | Description   | DMA Channel |
|---------|-----|--------|-------|-------|---------------|-------------|
| STAT    | 110 | PIXC   | 0     | LEVEL | Status        |             |
| CH1_DMA | 108 | PIXC   | 0     | LEVEL | Channel 1 DMA | 36          |
| CH0_DMA | 107 | PIXC   | 0     | LEVEL | Channel 0 DMA | 35          |
| CH2_DMA | 109 | PIXC   | 0     | LEVEL | Channel 2 DMA | 37          |

## Trigger List for PIXC module

**Table 32-9:** Trigger List for the PIXC Module

| Interrupt | ID | Module | Count | Type       | Description   | MS Type |
|-----------|----|--------|-------|------------|---------------|---------|
| CH1_DMA   | 58 | PIXC   | 0     | PULSE/EDGE | Channel 1 DMA | MASTER  |
| CH2_DMA   | 59 | PIXC   | 0     | PULSE/EDGE | Channel 2 DMA | MASTER  |
| CH0_DMA   | 57 | PIXC   | 0     | PULSE/EDGE | Channel 0 DMA | MASTER  |
| CH1_DMA   | 58 | PIXC   | 0     | N/A        | Channel 1 DMA | SLAVE   |
| CH2_DMA   | 59 | PIXC   | 0     | N/A        | Channel 2 DMA | SLAVE   |
| CH0_DMA   | 57 | PIXC   | 0     | N/A        | Channel 0 DMA | SLAVE   |

## PIXC Programming Model

The PIXC is able to take data in from either memory or the video subsystem. The output is able to go back to memory or piped back to the video subsystem. Thus, video subsystem needs to be configured correctly before enabling the use of the PIXC.

## PIXC Mode Configuration

This section describes typical mode configuration tasks for using the PIXC.

### Performing Data Overlay

Data overlay allows a separate image to be overlaid or blended with the main input image.

1. Define rectangular region in the input image to be covered by an overlay.
2. Define single DMA descriptor for the overlay transfer.
3. Configure overlay coordinate registers in PIXC (PIXC\_HSTART\_A, PIXC\_HEND\_A, PIXC\_VSTART\_A, and PIXC\_VEND\_A).
4. Configure transparency ratio register (PIXC TRANSP\_A).
5. Optionally define a second overlay region and configure PIXC\_HSTART\_B, PIXC\_HEND\_B, PIXC\_VSTART\_B, and PIXC\_VEND\_B and PIXC\_TRANS\_B accordingly.
6. Enable PIXC and overlay functionality by setting PIXC\_CTL.EN = 1, PIXC\_CTL.OVAEN = 1 and PIXC\_CTL.OVBEN = 1 (if a 2nd overlay region is defined).

*RESULT:*

The output image is blended with the overlay images at the specified overlay region.

### Performing Color Space Conversion Only

The PIXC can be used to color convert an image or frame from RGB to YUV or from YUV to RGB

1. Configure and set up input connection of the PIXC in the video sub-system to obtain the main input image.
2. Configure and set up output connection of the PIXC in the video sub-system to output the resulting output image.
3. Program the conversion component registers (PIXC\_CONRY, PIXC\_CONGU and PIXC\_CONBV) and conversion bias register (PIXC\_CCBIAS).
4. Enable the PIXC by setting PIXC\_CTL.EN = 1 but keeping the overlay enables off by setting PIXC\_CTL.OVAEN = 0 and PIXC\_CTL.OVBEN = 0.

*RESULT:*

Converts an input image from RGB to YUV or an image from YUV to RGB

## PIXC Register Descriptions

Pixel Compositor (PIXC) contains the following registers.

**Table 32-10:** PIXC Module Registers

| Name          | Description                           |
|---------------|---------------------------------------|
| PIXC_CTL      | Control Register                      |
| PIXC_PPL      | Pixels Per Line Register              |
| PIXC_LPF      | Line Per Frame Register               |
| PIXC_HSTART_A | Overlay A Horizontal Start Register   |
| PIXC_HEND_A   | Overlay A Horizontal End Register     |
| PIXC_VSTART_A | Overlay A Vertical Start Register     |
| PIXC_VEND_A   | Overlay A Vertical End Register       |
| PIXC_TRANSP_A | Overlay A Transparency Ratio Register |
| PIXC_HSTART_B | Overlay B Horizontal Start Register   |
| PIXC_HEND_B   | Overlay B Horizontal End Register     |
| PIXC_VSTART_B | Overlay B Vertical Start Register     |
| PIXC_VEND_B   | Overlay B Vertical End Register       |
| PIXC_TRANSP_B | Overlay B Transparency Ratio Register |
| PIXC_IRQSTAT  | Interrupt Status Register             |
| PIXC_CONRY    | RY Conversion Component Register      |
| PIXC_CONGU    | GU Conversion Component Register      |
| PIXC_CONBV    | BV Conversion Component Register      |
| PIXC_CCBIAS   | Conversion Bias Register              |
| PIXC_TC       | Transparency Color Register           |
| PIXC_REVID    | Revision Id                           |

## Control Register

The PIXC\_CTL register provides module enable, overlay enable, re-sampling mode selection, input/overlay/output data format selection, transparent color enable, and input/output RGB data format.

### PIXC\_CTL: Control Register - R/W

Reset = 0x0000 0000

**Figure 32-25:** PIXC\_CTL Register Diagram

**Table 32-11:** PIXC\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:10   | ORGBFRMT | Output RGB Data Format.<br>The PIXC_CTL.ORGBFRMT bits select the output RGB data format. This selection only is relevant when PIXC_CTL.OUTFRMT is set. |
|         |          | 0 RGB 888                                                                                                                                              |
|         |          | 1 Reserved                                                                                                                                             |
|         |          | 2 RGB 565                                                                                                                                              |
|         |          | 3 RGB 666                                                                                                                                              |

**Table 32-11:** PIXC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9:8     | IRGBFRMT | Input Image Channel RGB Data Format.<br>The <code>PIXC_CTL.IRGBFRMT</code> bits select the input image channel RGB data format. This selection only is relevant when <code>PIXC_CTL.IFRMT</code> is set. |
|         |          | 0      RGB 888                                                                                                                                                                                           |
|         |          | 1      Reserved                                                                                                                                                                                          |
|         |          | 2      RGB 565                                                                                                                                                                                           |
|         |          | 3      RGB 666                                                                                                                                                                                           |
| 7       | ENTC     | Enable Transparent Color.                                                                                                                                                                                |
|         |          | 0      Disable Transparent Color                                                                                                                                                                         |
|         |          | 1      Enable Transparent Color                                                                                                                                                                          |
| 6       | UDSMOD   | Up/Down Sampling Mode.<br>The <code>PIXC_CTL.UDSMOD</code> selects whether the PIXC either uses averaging for up/down sampling or uses duplicating for up sampling and dropping for down sampling.       |
|         |          | 0      Duplicating for up sampling and dropping for down sampling                                                                                                                                        |
|         |          | 1      Averaging for both up sampling and down sampling                                                                                                                                                  |
| 5       | OUTFRMT  | Output Data Format.<br>The <code>PIXC_CTL.OUTFRMT</code> selects YUV or RGB for the output format.                                                                                                       |
|         |          | 0      YUV Data Format                                                                                                                                                                                   |
|         |          | 1      RGB Data Format                                                                                                                                                                                   |
| 4       | OVFRMT   | Overlay Data Format.<br>The <code>PIXC_CTL.OVFRMT</code> selects YUV or RGB for the overlay format.                                                                                                      |
|         |          | 0      YUV Data Format                                                                                                                                                                                   |
|         |          | 1      RGB Data Format                                                                                                                                                                                   |

**Table 32-11:** PIXC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | IFRMT    | Image Data Format.<br>The <code>PIXC_CTL.IFRMT</code> selects YUV or RGB for the input format.                                                      |
|         |          | 0 YUV Data Format                                                                                                                                   |
|         |          | 1 RGB Data Format                                                                                                                                   |
| 2       | OVENB    | Overlay Block B Enable.<br>If both <code>PIXC_CTL.OVENA</code> and <code>PIXC_CTL.OVENB</code> are cleared, only color space conversion is enabled. |
|         |          | 0 Disable                                                                                                                                           |
|         |          | 1 Enable                                                                                                                                            |
| 1       | OVENA    | Overlay Block A Enable.<br>If both <code>PIXC_CTL.OVENA</code> and <code>PIXC_CTL.OVENB</code> are cleared, only color space conversion is enabled. |

|         |          | 1 Enable                                                                                                                                            |
| 0       | EN       | Overlay Manager enable (module enable).<br>The <code>PIXC_CTL.EN</code> bit enables the PIXC.                                                       |
|         |          | 0 Disable                                                                                                                                           |
|         |          | 1 Enable                                                                                                                                            |

## Pixels Per Line Register

The `PIXC_PPL` register provides the number of pixels per line of the display.

**PIXC\_PPL: Pixels Per Line Register - R/W**

Reset = 0x0000

**Figure 32-26:** PIXC\_PPL Register Diagram

Table 32-12: PIXC\_PPL Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 15:0    | VALUE    | Pixels Per Line of the Display. |

Line Per Frame Register

The PIXC\_LPF register provides the number of lines per frame of the display.

PIXC\_LPF: Line Per Frame Register - R/W

Reset = 0x0000

Figure 32-27: PIXC\_LPF Register Diagram

Table 32-13: PIXC\_LPF Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 15:0    | VALUE    | Lines Per Frame of the Display. |

Overlay A Horizontal Start Register

The PIXC\_HSTART\_A register provides the horizontal start pixel coordinates of overlay A data.

PIXC\_HSTART\_A: Overlay A Horizontal Start Register - R/W

Reset = 0x0000

Figure 32-28: PIXC\_HSTART\_A Register Diagram

**Table 32-14:** PIXC\_HSTART\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration                                 |
|---------|----------|---------------------------------------------------------|
| 15:0    | VALUE    | Horizontal Start Pixel Coordinates of the Overlay Data. |

## Overlay A Horizontal End Register

The PIXC\_HEND\_A registers provides the horizontal end pixel coordinates of overlay A data.

**PIXC\_HEND\_A: Overlay A Horizontal End Register - R/W**

Reset = 0x0000

**Figure 32-29:** PIXC\_HEND\_A Register Diagram

**Table 32-15:** PIXC\_HEND\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration                               |
|---------|----------|-------------------------------------------------------|
| 15:0    | VALUE    | Horizontal End Pixel Coordinates of the Overlay Data. |

## Overlay A Vertical Start Register

The PIXC\_VSTART\_A registers provides the vertical start pixel coordinates of overlay A data.

**PIXC\_VSTART\_A: Overlay A Vertical Start Register - R/W**

Reset = 0x0000

**Figure 32-30:** PIXC\_VSTART\_A Register Diagram

Table 32-16: PIXC\_VSTART\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration                               |
|---------|----------|-------------------------------------------------------|
| 15:0    | VALUE    | Vertical Start Pixel Coordinates of the Overlay Data. |

Overlay A Vertical End Register

The PIXC\_VEND\_A register provides the vertical end pixel coordinates of overlay A data.

PIXC\_VEND\_A: Overlay A Vertical End Register - R/W

Reset = 0x0000

Figure 32-31: PIXC\_VEND\_A Register Diagram

Table 32-17: PIXC\_VEND\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration                             |
|---------|----------|-----------------------------------------------------|
| 15:0    | VALUE    | Vertical End Pixel Coordinates of the Overlay Data. |

Overlay A Transparency Ratio Register

The PIXC TRANSP\_A register provides overlay A transparency ratio values.

PIXC\_TRANSP\_A: Overlay A Transparency Ratio Register - R/W

Reset = 0x000f

Figure 32-32: PIXC\_TRANSP\_A Register Diagram

**Table 32-18:** PIXC TRANSP\_A Register Fields

| Bit No. | Bit Name | Description/Enumeration            |
|---------|----------|------------------------------------|
| 3:0     | VALUE    | Overlay Transparency Ratio Values. |

## Overlay B Horizontal Start Register

The PIXC\_HSTART\_B register provides the horizontal start pixel coordinates of overlay B data.

**PIXC\_HSTART\_B: Overlay B Horizontal Start Register - R/W**

Reset = 0x0000

**Figure 32-33:** PIXC\_HSTART\_B Register Diagram

**Table 32-19:** PIXC\_HSTART\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration                                 |
|---------|----------|---------------------------------------------------------|
| 15:0    | VALUE    | Horizontal Start Pixel Coordinates of the Overlay Data. |

## Overlay B Horizontal End Register

The PIXC\_HEND\_B registers provides the horizontal end pixel coordinates of overlay B data.

**PIXC\_HEND\_B: Overlay B Horizontal End Register - R/W**

Reset = 0x0000

**Figure 32-34:** PIXC\_HEND\_B Register Diagram

Table 32-20: PIXC\_HEND\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration                               |
|---------|----------|-------------------------------------------------------|
| 15:0    | VALUE    | Horizontal End Pixel Coordinates of the Overlay Data. |

Overlay B Vertical Start Register

The PIXC\_VSTART\_B registers provides the vertical start pixel coordinates of overlay B data.

PIXC\_VSTART\_B: Overlay B Vertical Start Register - R/W

Reset = 0x0000

Figure 32-35: PIXC\_VSTART\_B Register Diagram

Table 32-21: PIXC\_VSTART\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration                               |
|---------|----------|-------------------------------------------------------|
| 15:0    | VALUE    | Vertical Start Pixel Coordinates of the Overlay Data. |

Overlay B Vertical End Register

The PIXC\_VEND\_B register provides the vertical end pixel coordinates of overlay B data.

PIXC\_VEND\_B: Overlay B Vertical End Register - R/W

Reset = 0x0000

Figure 32-36: PIXC\_VEND\_B Register Diagram

**Table 32-22:** PIXC\_VEND\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration                             |
|---------|----------|-----------------------------------------------------|
| 15:0    | VALUE    | Vertical End Pixel Coordinates of the Overlay Data. |

## Overlay B Transparency Ratio Register

The PIXC TRANSP\_B register provides overlay B transparency ratio values.

**PIXC\_TRANSP\_B: Overlay B Transparency Ratio Register - R/W**

Reset = 0x000f

**Figure 32-37:** PIXC\_TRANSP\_B Register Diagram

**Table 32-23:** PIXC\_TRANSP\_B Register Fields

| Bit No. | Bit Name | Description/Enumeration            |
|---------|----------|------------------------------------|
| 3:0     | VALUE    | Overlay Transparency Ratio Values. |

## Interrupt Status Register

The PIXC\_IRQSTAT register provides overlay interrupt configuration and status information.

**PIXC\_IRQSTAT: Interrupt Status Register - R/W**

Reset = 0x0000

**Figure 32-38:** PIXC\_IRQSTAT Register Diagram

Table 32-24: PIXC\_IRQSTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | FRMSTAT  | Frame Interrupt Status.<br>The PIXC_IRQSTAT.FRMSTAT indicates an end of frame condition for the PIXC. This status bit is write-1-to-clear.               |
| 2       | OVSTAT   | Overlay Interrupt Status.<br>The PIXC_IRQSTAT.OVSTAT indicates an end of last valid overlay condition for the PIXC. This status bit is write-1-to-clear. |
| 1       | FRMEN    | Frame Interrupt Enable.<br>The PIXC_IRQSTAT.FRMEN enables the PIXC end of frame interrupt.                                                               |
|         |          | 0                      Disable                                                                                                                           |
|         |          | 1                      Enable                                                                                                                            |
| 0       | OVEN     | Overlay Interrupt Enable.<br>The PIXC_IRQSTAT.OVEN enables the PIXC end of last valid overlay interrupt.                                                 |
|         |          | 0                      Disable                                                                                                                           |
|         |          | 1                      Enable                                                                                                                            |

RY Conversion Component Register

The PIXC\_CONRY register provides the R/Y conversion coefficients in the color space conversion matrix.

Figure 32-39: PIXC\_CONRY Register Diagram

**Table 32-25:** PIXC\_CONRY Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 30      | RYMULT4  | Multiply the Row by 4.                 |
|         |          | 0      Disable                         |
|         |          | 1      Enable                          |
| 29:20   | A13      | A13 element in the coefficient matrix. |
| 19:10   | A12      | A12 element in the coefficient matrix. |
| 9:0     | A11      | A11 element in the coefficient matrix. |

## GU Conversion Component Register

The PIXC\_CONGU register provides the G/U conversion coefficients in the color space conversion matrix.

### PIXC\_CONGU: GU Conversion Component Register - R/W

Reset = 0x0000 0000

**Figure 32-40:** PIXC\_CONGU Register Diagram

**Table 32-26:** PIXC\_CONGU Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 30      | GUMULT4  | Multiply The Row By 4.  |
|         |          | 0      Disable          |
|         |          | 1      Enable           |

Table 32-26: PIXC\_CONGU Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                          |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 29:20   | A23      | A23 element in the coefficient matrix.                                                                                                           |
| 19:10   | A22      | A22 element in the coefficient matrix.                                                                                                           |
| 9:0     | A21      | A21 element in the coefficient matrix.<br>The PIXC_CONGU register provides the B/V conversion coefficients in the color space conversion matrix. |

BV Conversion Component Register

PIXC\_CONBV: BV Conversion Component Register - R/W

Reset = 0x0000 0000

Figure 32-41: PIXC\_CONBV Register Diagram

Table 32-27: PIXC\_CONBV Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 30      | BVMULT4  | Multiply The Row By 4.                 |
|         |          | 0 Disable                              |
|         |          | 1 Enable                               |
| 29:20   | A33      | A33 element in the coefficient matrix. |
| 19:10   | A32      | A32 element in the coefficient matrix. |

**Table 32-27:** PIXC\_CONBV Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 9:0     | A31      | A31 element in the coefficient matrix. |

Conversion Bias Register

The PIXC\_CCBIAS register provides the bias values in the color space conversion matrix.

**PIXC\_CCBIAS: Conversion Bias Register - R/W**

Reset = 0x0000 0000

**Figure 32-42:** PIXC\_CCBIAS Register Diagram

**Table 32-28:** PIXC\_CCBIAS Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 29:20   | A34      | A34 in bias vector.     |
| 19:10   | A24      | A24 in bias vector.     |
| 9:0     | A14      | A14 in bias vector.     |

Transparency Color Register

The PIXC\_TC register provides the transparent color value.

PIXC\_TC: Transparency Color Register - R/W

Reset = 0x0000 0000

Figure 32-43: PIXC\_TC Register Diagram

Table 32-29: PIXC\_TC Register Fields

| Bit No. | Bit Name | Description/Enumeration       |
|---------|----------|-------------------------------|
| 23:16   | BVT      | Trans. color - B/V component. |
| 15:8    | GUT      | Trans. color - G/U component. |
| 7:0     | RYT      | Trans. color - R/Y component. |

Revision Id

The PIXC\_REVID register provides the PIXC module revision information.

PIXC\_REVID: Revision Id - R/NW

Reset = 0x0000 0020

Figure 32-44: PIXC\_REVID Register Diagram

**Table 32-30:** PIXC\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:4     | MAJOR    | Major Version ID.       |
| 3:0     | REV      | Incremental Version ID. |

## 33 Reset Control Unit (RCU)

Reset is the initial state of the whole processor or one of the cores and is the result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system reset starts with Core-0 only being ready to boot. Exiting a Core n only reset starts with this Core n being ready to boot.

The reset control unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This is particularly important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset).

### RCU Register List

The reset control unit (RCU) controls how all the functional units in the processor enter and exit Reset. Differences in functional requirements and clocking constraints (units in different clock domains have to enter reset asynchronously, but units exit reset in a deterministic way) define how reset signals are generated. Reset signals propagate through all the functional units asynchronously. For more information on RCU functionality, see the RCU register descriptions.

**Table 33-1:** RCU Module Registers

| Name          | Description                       |
|---------------|-----------------------------------|
| RCU_CTL       | Control Register                  |
| RCU_STAT      | Status Register                   |
| RCU_CRCTL     | Core Reset Control Register       |
| RCU_CRSTAT    | Core Reset Status Register        |
| RCU_SIDIS     | System Interface Disable Register |
| RCU_SISTAT    | System Interface Status Register  |
| RCU_SVECT_LCK | SVECT Lock Register               |
| RCU_BCODE     | Boot Code Register                |

**Table 33-1:** RCU Module Registers (Continued)

| Name       | Description                |
|------------|----------------------------|
| RCU_SVECTn | Software Vector Register n |

## ADSP-BF60x RCU Trigger List

**Table 33-2:** Masters ADSP-BF60x RCU Trigger List

| Description | ID | Sensitivity |
|-------------|----|-------------|
|             |    |             |

**Table 33-3:** Slaves ADSP-BF60x RCU Trigger List

| Description         | ID | Sensitivity |
|---------------------|----|-------------|
| RCU0 System Reset 0 | 0  |             |
| RCU0 System Reset 1 | 1  |             |
|                     |    |             |

## RCU Definitions

To make the best use of the RCU, it is useful to understand the terms in this section.

The following are Resets that are defined by their target

### Hardware Reset

All functional units are set to their default states, no exception. History is lost.

### System Reset

All functional units except the RCU are set to their default states.

### Core n Only Reset

Affects Core n only. The system software should guarantee that the core in reset state is not accessed by any bus master.

The following are Resets that are defined by their source

## Hardware Reset

The  $\overline{\text{RESET}}$  input signal is asserted active (pulled low).

## System Reset

May be triggered by software (writing to `RCU_CONTROL`) or by another functional unit such as the DPM (Hibernate) or any of the generic reset inputs.

## Core n Only Reset

Triggered by software.

# RCU Architectural Concepts

The following sections provide details about the Reset Control Unit Architecture.

## Reset Sources

The RCU provides the hardware that controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints (for example units in different clock domains have to enter reset asynchronously but exit reset in a deterministic way) define how reset signals are generated. It is the program's responsibility to guarantee that none of the reset functions put the system in an undefined state or cause resources to stall. This is particularly important when only one of the cores is reset because the program needs to guarantee that there is no pending system activity involving Core n (for example no pending transactions to core n) before it is reset. The following table defines how reset sources affect the different functional units.

| Reset Source                           | Reset Type     | Affected Functional Units                                                                                                                                                       |
|----------------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\overline{\text{RESET}}$              | Hardware Reset | All functional units except RTC (if present)                                                                                                                                    |
| Hibernate Reset                        | System Reset   | All functional units except RTC (if present), <code>RCU_STAT</code> and the units on the <code>VDDEXT</code> power domain                                                       |
| <code>SYSCLK</code> Clock Domain Reset | System Reset   | All functional units except RTC (if present), <code>RCU_STAT</code> , <code>RCU_BCODE</code> , <code>RCU_CRCTL.CRn</code> and the units on the <code>VDDEXT</code> power domain |
| <code>SCLK0</code> Clock Domain Reset  | System Reset   | All functional units except <code>RCU_STAT</code> , <code>RCU_BCODE</code> , <code>RCU_CRCTL.CRn</code> and the units on the <code>VDDEXT</code> power domain                   |

| Reset Source                                                               | Reset Type      | Affected Functional Units                                                                                                 |
|----------------------------------------------------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| SCLK1 Clock Domain Reset                                                   | System Reset    | All functional units except RTC (if present), RCU_STAT, RCU_BCODE, RCU_CRCTL.CRn and the units on the VDDEXT power domain |
| RCU_CTL.SYSRST<br>System Reset (Software Triggered Reset)                  | System Reset    | All functional units except RTC (if present), RCU_STAT, RCU_BCODE, RCU_CRCTL.CRn and the units on the VDDEXT power domain |
| RCU_CRCTL.CRn bit set<br>(Software Triggered Reset) ( $15 \geq n \geq 0$ ) | Core Only Reset | Core n Only                                                                                                               |

## RCU Status and Error Signals

The RCU\_STAT register reflects status and error information. There are three kinds of errors that can occur in the RCU. The Reset Out error is triggered if RSTOUT is both asserted and deasserted at the same time. The Lock Write error occurs if an attempt is made to write a lock RCU register. The Address Error occurs if a read only register is written to or if an attempt is made to a reserved address within the RCU MMR address range.

## Resetting a Core

The RCU allows reset of a given core n using another core.

### PREREQUISITE:

Core n can be individually reset by software, either setting any of CRn ( $15 \geq n \geq 0$ ) bits in RCU\_CRCTL register. Cores that reset themselves will not be able to guarantee that all the system transactions to or from it have completed. Although a core n reset can be triggered by core n itself it is recommended that it is triggered by another core. Core n may be reset to restore its functionality when it cannot execute software. The suggested sequence to reset core n only is shown below.

1. Clear the RCU\_CRSTAT.CRn bit.
2. Disable interrupts to core n
3. Set the RCU\_SIDIS.SIn bit to disable core n's interfaces in order to stop DMA accesses to its L1, stop core n's accesses to memory, and stop accesses to MMRs.
4. Test the RCU\_SISTAT.SIn bit to detect when accesses to core n have been disabled and all the pending transactions have completed.
5. Set the RCU\_CRCTL.Rn bit to reset core n.

6. Poll the `RCU_CRSTAT.CRn` bit until core `n` is in reset.
7. Once the core is in reset, clear the `RCU_SIDIS.SIn` bit to re-enable the core interfaces.
8. Clear the `RCU_CRCTL.Rn` bit to take core `n` out of reset.
9. Poll the `RCU_CRSTAT.CRn` bit until core `n` is out of reset.

## BF60x Specific Information

The following information specific to BF60x processors should be kept in mind when reading this chapter:

- There are two cores, core 0 and core 1
- There is no RTC (real-time clock)
- The only SCLK0 domain source of system reset is the SDU
- There is no SCLK1 source of system reset
- The SYSCLK sources of system reset are TRU and SEC

## RCU Register Descriptions

Reset Control Unit (RCU) contains the following registers.

**Table 33-4:** RCU Module Registers

| Name          | Description                             |
|---------------|-----------------------------------------|
| RCU_CTL       | Control Register                        |
| RCU_STAT      | Status Register                         |
| RCU_CRCTL     | Core Reset Control Register             |
| RCU_CRSTAT    | Core Reset Status Register              |
| RCU_SIDIS     | System Interface Disable Register       |
| RCU_SISTAT    | System Interface Status Register        |
| RCU_SVECT_LCK | SVECT Lock Register                     |
| RCU_BCODE     | Boot Code Register                      |
| RCU_SVECTn    | Software Vector Register <code>n</code> |

## Control Register

The RCU control register (RCU\_CTL) provides a register lock, controls for the system reset pin, and a control for system reset.

**RCU\_CTL: Control Register - R/W**

Reset = 0x0000 0000

**Figure 33-1:** RCU\_CTL Register Diagram

**Table 33-5:** RCU\_CTL Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                     |                 |
|---------|------------|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 31      | LOCK       | Lock.<br>If the global lock bit is set (SPU_CTL_GLCK bit =1) and the RCU_CTL . LOCK bit is set, the RCU_CTL register is read only (locked). |                 |
|         |            | 0                                                                                                                                           | Unlock          |

## Status Register

The RCU status register (RCU\_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can be cleared by software. Error status bits are cleared by any reset event.

### RCU\_STAT: Status Register - R/W

Reset = 0x0000 0021

**Figure 33-2:** RCU\_STAT Register Diagram

**Table 33-6:** RCU\_STAT Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                       |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18      | RSTOUTERR | Reset Out Error.<br>The RCU_STAT.RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL.RSTOUTASRT and RCU_CTL.RSTOUTDSRT simultaneously. This condition triggers a bus error.                                                            |
|         |           | 0 No Error                                                                                                                                                                                                                                                    |
|         |           | 1 Error Occurred                                                                                                                                                                                                                                              |
| 17      | LWERR     | Lock Write Error.<br>The RCU_STAT.LWERR bit indicates (when set) there was an attempted write to an RCU register while the the RCU_CTL.LOCK bit was set and the global lock bit is enabled (SPU_CTL_GLCK bit =1). This status bit is sticky; write-1-to-clear |
|         |           | 0 No Error                                                                                                                                                                                                                                                    |
|         |           | 1 Error Occurred                                                                                                                                                                                                                                              |
| 16      | ADDRERR   | Address Error.<br>The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.                                                                                                                 |
|         |           | 0 No Error                                                                                                                                                                                                                                                    |
|         |           | 1 Error Occurred                                                                                                                                                                                                                                              |
| 11:8    | BMODE     | Boot Mode.<br>The RCU_STAT.BMODE bits indicate the input on the boot mode pins.                                                                                                                                                                               |
| 5       | RSTOUT    | Reset Out Status.<br>The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.                                                                                                                                                          |
|         |           | 0 RSTOUT Deasserted                                                                                                                                                                                                                                           |
|         |           | 1 RSTOUT Asserted                                                                                                                                                                                                                                             |

## Core Reset Control Register

The RCU core reset control n registers (RCU\_CRCTL) include a lock bit (RCU\_CRCTL.LOCK) and a core reset bit (RCU\_CRCTL.CRn) for each processor core on the product.

RCU\_CRCTL: Core Reset Control Register - R/W

Reset = 0x0000 0002

Figure 33-3: RCU\_CRCTL Register Diagram

Table 33-7: RCU\_CRCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                         |                        |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| 31      | LOCK     | Lock.<br>If the global lock bit is set (SPU_CTL_GLCK bit =1) and the RCU_CRCTL . LOCK bit is set, the RCU_CRCTL register is read only (locked). |                        |
|         |          | 0                                                                                                                                               | Unlock                 |
|         |          | 1                                                                                                                                               | Lock                   |
| 1:0     | CRn      | Core Reset n.<br>The RCU_CRCTL . CRn bit resets processor core n.                                                                               |                        |
|         |          | 0                                                                                                                                               | Inactive               |

| 31:0    | RVECT    | Reset Vector.           |

# 34 Booting the Processor (Boot)

This section provides an overview of the process of booting. **Notice of Changes:** This documentation contains material that is subject to change without notice. The content of the boot ROM as well as hardware behavior may change across silicon revisions. See the anomaly list for differences between silicon revisions.

When the `RESET` input signal releases, the processor starts fetching and executing from the on-chip boot ROM from the bottom of L2 ROM.

The internal boot ROM includes a boot kernel that loads the processor according to a boot stream provided in external memory or via a supported peripheral. A boot stream is generally produced using the loader utility provided with the tools. The boot stream consists of a series of blocks that can instruct the boot kernel to perform the functions described in this chapter, including:

- Loading memory with provided data or code
- Initializing memory
- Initializing peripherals
- Verifying checksum
- Decompress data
- Forward data to a peripheral

**NOTE:** All available peripherals are not supported by the boot kernel, for more information, see specific boot modes

The boot stream is processed in sequence until a block marked as the final block is processed. After the final block is processed the boot kernel jumps to the start of the program location. An application generally starts at address `0xFFA0000` unless otherwise specified.

The source of the boot kernel is determined by which boot mode is selected. A boot mode is specified by setting the four dedicated `BMODE` input pins.

## Boot Loader Stream

A loader stream is a set of formatted blocks containing instructions for the boot kernel, as well as the application and data to be loaded to the chip. This section describes in detail different aspects of the stream, its blocks, and some common use cases.

Each block begins with a block header which contains attributes of the block as well as flags to control its processing by the boot ROM. On power-up or reset the processor begins executing the on-chip boot ROM and the boot stream is either read from memory or received from a peripheral, depending on the boot mode specified. Each block in the boot stream instructs the boot kernel to perform some action, most commonly to simply load data to a specified location. Other actions include running code that initializes a peripheral, forwarding data to a peripheral, or processing data then loading it to a location.

A loader stream must always begin with a First block, and end with a Final block.

As the Project Flow figure illustrates, the tools suite includes a loader utility (loader.exe). The loader utility parses an input executable file (.dxe), and creates a set of blocks representing the segmented application. The output is stored in a loader file (.ldr). The loader file contains the boot stream and is made available to hardware by programming or burning it into non-volatile external memory, or sending it through a peripheral during boot time. Refer to the Loader Manual for details on loader usage.

**Figure 34-1:** Project Flow

The [Booting Process](#) figure shows the parallel or serial boot stream contained in a flash memory device. In host boot scenarios, the non-volatile memory usually connects to the host processor rather than directly to the processor. After reset the headers are read and parsed by the on-chip boot kernel and the loader stream is processed block by block. Finally, payload data is copied to destination addresses, either in on-chip L1 and L2 memory, or off-chip to SDRAM or SRAM.

**Figure 34-2:** Booting Process

In some cases (for example when the BLFAG\_INDIRECT flag for any block is set), the boot kernel uses another memory block in L1 data bank B for intermediate data storage. To avoid conflicts, the elfloader utility ensures this region is booted last.

The entire source code of the boot ROM is shipped with the tools. The source code can be reviewed for information not covered in this manual. Note that minor maintenance work may be required to the boot ROM code if silicon is updated.

## Block Structure

**Figure 34-3:** Boot Header

A boot stream consists of multiple boot blocks as shown in the figure. Every block is headed by a 16-byte block header. The 16 bytes are functionally grouped into four 32-bit words: the block code, target address, byte count, and the argument field. This section describes the fields in general. The uses may vary

depending on the particular block type and boot mode, refer to the block type descriptions and boot modes for further information.

## Block Code

**Table 34-1:** Block Header flags

| Bit   | Name            | Description                                                                                                                                          |
|-------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-3   | BCODE           | Specific to boot modes (see Boot Modes)                                                                                                              |
| 4     | BFLAG_SAVE      | Saves the memory of this block to off-chip memory in case of power failure or a hibernate request. This flag is not used by the on-chip boot kernel. |
| 5     | BFLAG_AUX       | Nests special block types as required by special-purpose second-stage loaders. This flag is not used by the on-chip boot kernel.                     |
| 6     | reserved        |                                                                                                                                                      |
| 7     | BFLAG_FORWARD   | Forward payload to a device. Must be used in conjunction with the BFLAG_INDIRECT flag.                                                               |
| 8     | BFLAG_FILL      | Fill the target location with a specified value.                                                                                                     |
| 9     | BFLAG_QUICKBOOT | Does not process block for a quick boot (warm boot).                                                                                                 |
| 10    | BFLAG_CALLBACK  | Calls function at the address provided.                                                                                                              |
| 11    | BFLAG_INIT      | Calls function at target address after loading payload to the same address                                                                           |
| 12    | BFLAG_IGNORE    | Block is ignored.                                                                                                                                    |
| 13    | BFLAG_INDIRECT  | Boots to an intermediate storage place.                                                                                                              |
| 14    | BFLAG_FIRST     | Indicates the block to be the first block of a new dxs                                                                                               |
| 15    | BFLAG_FINAL     | Indicates the last block of a loader stream. Booting will complete after processing the block.                                                       |
| 16-23 | HDRCHK          | A simple XOR checksum of the other 31 bytes in the boot block header.                                                                                |
| 24-31 | HDRSIGN         | 0xAD (dependent on processor family)                                                                                                                 |

## TARGET\_ADDRESS

The `TARGET_ADDRESS` holds the address that the block applies to, (where the code or data should be loaded). However, the field is interpreted differently depending on what specific flags are set in the block code. Refer to each Block Type's documentation for details.

The following attributes must be true:

- The target address must be divisible by 4, as the boot kernel uses 32-bit DMA for certain operations.
- The target address must point to valid on-chip or off-chip memory locations.
- The `BFLAG_INDIRECT` flag must be set if the target address points to L1 instruction memory. For performance reasons, this is also recommended when booting to off-chip memory.

**NOTE:** Booting into scratchpad memory is not supported. If booting to scratchpad memory is attempted, the processor hangs within the on-chip boot ROM. Similarly, booting into the upper 16 bytes of L1 data bank A is not supported. These memory locations are used by the kernel for intermediate storage of block header information. These memory regions cannot be initialized at boot time. After booting, they can be used by the application during runtime.

## BYTE\_COUNT

The byte count must be divisible by 4, and also may be zero. This 32-bit field generally holds the size of the block. In some cases it can be used differently (such as when `BFLAG_FILL` is set). See the block types section for information on specific variations.

## ARGUMENT

The 32-bit field is a user variable for most block types. The value is accessible by the initcode or the callback routine and can therefore be used for optional instructions to these routines.

The `ARGUMENT` field is used in different ways by different block types. See the block type descriptions for further information.

## Block Types

Describes how to use different types of loader blocks.

A loader stream is a set of linked blocks and each block is responsible for performing a certain function dependent on the block's type. A block type is defined by its flags in the block header. Operations include functions such as loading data, filling a memory region with data, forwarding data to a peripheral, and instructing the kernel to stop processing. This section describes each block type and how it is used within a boot loader stream.

## Normal Block

A block's primary function is to load some data into a specified location of memory. A normal block instructs the boot kernel to load the data contained in its payload to the location specified in the `TARGET_ADDRESS` field. The `BYTE_COUNT` defines the size of the payload, once the correct amount of data has been loaded, the kernel moves on to process the next block in the stream.

**Table 34-2:** Flags

| Flag                        | Required Value |                                                 |
|-----------------------------|----------------|-------------------------------------------------|
| <code>TARGET_ADDRESS</code> | Y              | Address where payload is loaded (must be valid) |
| <code>BYTE_COUNT</code>     | Y              | Size of block in bytes                          |

## First Block

A first block indicates the start of a DXE and is always required at the beginning of a loader stream. In the case of a loader stream that contains *Multi-DXE Boot Streams*, a first block occurring within the loader indicates the beginning of a new DXE.

When the kernel processes the first block in a loader stream, the `TARGET_ADDRESS` also updates the `EVT1` register. This register contains the start address of the application.

**NOTE:** Note that a First Block cannot be combined with a Fill Block

**Table 34-3:** Flags

| Flag                        | Required Value |                                                                                                                                                                                                               |
|-----------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BFLAG_FIRST</code>    | Y              | 1                                                                                                                                                                                                             |
| <code>ARGUMENT</code>       | Y              | Offset to the next DXE, or first address following loader stream                                                                                                                                              |
| <code>TARGET_ADDRESS</code> | Y              | When the block is the first block in a loader stream, also defines the start address for the application. If the block is not the first in a loader stream the target address is used as in normal operation. |

## Final Block

The final block marks the last block in a boot stream (not a DXE). After processing a final block the boot kernel jumps to the application's start address. By default this is performed by jumping to the vector stored in the `EVT1` register. The boot kernel provides options to execute an `RTS` instruction or a `RAISE 1` instruc-

tion. The default behavior can be changed by an initcode routine, or by the kernel's boot routine API. The EVT1 register is updated by the boot kernel when processing the first block in the loader stream.

Before the boot kernel passes program control to the application it does some housekeeping. Most of the registers that were used are put in their default state. However, some register values may differ depending on the boot mode. See Boot Modes for more information. The following DMA configuration registers and primary register control registers (UART\_CTL, SPI\_CTL, HOST\_CONTROL for example) are restored, while others are purposely not restored. For example SPI\_CLK.BAUD and UART\_CLK remain unchanged so that the settings obtained during the boot process are not lost.

**Table 34-4:** Flags

| Flag        | Required Value |   |
|-------------|----------------|---|
| BFLAG_FINAL | Y              | 1 |

## Indirect Block

An intermediate block is first loaded to a storage location before being copied to the destination. This functionality is motivated by the following situations:

- Some boot modes may not use DMA. The core cannot access some memory locations directly (L1 instruction SRAM), and some it cannot access efficiently. An intermediate load to a different location improves overall efficiency.
- In some booting scenarios the data in the payload needs to be operated on or analyzed before it is fully loaded (such as decryption or checksum calculation). By using an intermediate location such scenarios are simplified and can be more efficient when loading to off-chip memories (see Callback Block).

In some cases a boot block may not fit into temporary storage memory so having a larger buffer may improve boot performance. If an entire block cannot fit into the buffer it is processed in pieces. Initialization code or callback functions can alter the temporary buffer region, including its location and size, by modifying the pTempBuffer and dTempByteCount variables in the [STRUCT\\_ROM\\_BOOT\\_CONFIG](#) structure. The default region is at the upper end of a physical memory block. When the size is changed from the default, keep in mind that it is already at the end of a memory block, so the beginning address pTempBuffer must also be modified.

**Table 34-5:** Flags

| Flag           | Required Value |                                                                                                     |
|----------------|----------------|-----------------------------------------------------------------------------------------------------|
| BFLAG_INDIRECT | Y              | 1                                                                                                   |
| BFLAG_CALLBACK | N              | Defines a callback function to operate on intermediate data. These 2 flags are often used together. |

## Ignore Block

An ignore block is a block that is (in most cases) ignored by the loader stream. Ignore blocks are useful when it's not possible to pass information in another block header. For example, if the first block contains data rather than application code, then inserting a first block with the correct application start address ensures the correct start address is used. Since this block has no other function it should be marked as an ignore block so that the kernel will not attempt to process any payload.

**Table 34-6:** Flags

| Flag         | Required Value |                                      |
|--------------|----------------|--------------------------------------|
| BFLAG_IGNORE | Y              | 1                                    |
| BYTE_COUNT   | Y              | Size of block to ignore, may be zero |

## Init Block

An init (initialization) block instructs the boot kernel to issue a `CALL` instruction to the target address after the entire block has been loaded. The function called is referred to as the *initcode routine*. If the initcode routine has been previously loaded, the block may declare a zero-size and have no payload.

Initcode routines can be used to speed up and customize booting mechanisms exposed by the boot kernel. Traditionally, an initcode routine is used to setup system PLL, bit rates, wait states, and the SDRAM controller. If executed early in the boot process, the boot time can be significantly reduced.

Initcode routines are required to follow the C language calling conventions. The expected C prototype is:

```
void initcode(STRUCT_ROM_BOOT_CONFIG* pBootStruct)
```

When programming in assembly, be certain to return using an `RTS` instruction. See the *C/C++ Compiler and Library Manual* for more information.

The struct provided to the initcode routine by the boot kernel contains a variety of information about the block being processed. This includes header information, locations of temporary block data (for indirect blocks), target address, and byte count. See the

In the simplest case, an initcode routine consists of only a single block in which the `BFLAG_INIT` flag is set. For larger routines, a sequence of blocks can incrementally load the routine, and only the last block should set the `BFLAG_INIT` flag. In the latter case, the last block should be of size zero, and simply instruct the boot kernel to issue the `CALL` instruction.

An initcode routine can be overwritten by a successive block if it is no longer needed, otherwise the routine can be called at multiple points during the boot process, and even remain in memory after booting is completed for use by the application.

**NOTE:** The following list provides requirements for initcode that is written in C or C++.

- Ensure the initcode routine does not contain calls to the run-time libraries
- Do not assume that parts of the run-time environment, such as the heap, are fully functional
- Ensure that all run-time components are loaded and initialized before the routine executes

The *loader* utility and tool set provide mechanisms to aid in implementing init codes and organizing them properly within the boot loader stream. A special project type is provided to allow the creation of initcode routines as separate projects. Options are available to assign particular pieces of the application to be initcode routines. For details and more information on the utility, see the *Loader Utility Manual*.

Initcode routine examples, including SDRAM controller initialization, can be found in the examples section

**Table 34-7:** Flags

| Flag           | Required Value |                                                                              |
|----------------|----------------|------------------------------------------------------------------------------|
| BFLAG_INIT     | Y              | 1                                                                            |
| TARGET_ADDRESS | Y              | Location to load payload data. CALL instruction issued to the same location. |
| ARGUMENT       | N              | Can be used to supply block specific arguments                               |
| BYTE_COUNT     | Y              | Size of payload, may be zero                                                 |

## Callback Block

A callback block instructs the boot kernel to call a pre-registered function upon completion of loading the block's payload. The purpose of a callback routine is to apply standard processing to the block payload. The callback routine is registered through an initcode routine prior to loading a block using the routine. Typically, callback routines contain checksum, decryption, decompression or hash algorithms.

To register a callback an init block must be created whose initcode modifies the `pCallbackFunction` pointer in the `STRUCT_ROM_BOOT_CONFIG` structure. A callback routine must be registered before a callback block can be processed.

Since callback routines require access to the payload data of the boot blocks, the block data must be loaded before it can be processed. Often an INDIRECT block is used in combination with a callback block.

Callback routines are expected to meet the C language calling conventions. For more information see the *C/C++ Compiler and Library Manual*. The prototype is as follows: `int32_t CallbackFunction(struct STRUCT_ROM_BOOT_CONFIG* pBootStruct, ADI_BOOT_BUFFER* pCallbackStruct, int32_t dCbFlags)`

The `pBootStruct` argument contains the `STRUCT_ROM_BOOT_CONFIG` information, and the `pCallbackStruct` contains the target address and size of the block (may vary when using indirect). The `dCbFlags` parameter is specifically used when indirect is also used. The `CBFLAG_DIRECT` flag indicates that the `BFLAG_INDIRECT` bit is not active and so that the callback routine is only called once per block. When the `CBFLAG_DIRECT` is set, the `CBFLAG_FIRST` and `CBFLAG_FINAL` are also set.

```
#define CBFLAG_FINAL 0x8  #define CBFLAG_FIRST 0x4  #define CBFLAG_DIRECT 0x1
```

See the Data Structures section for more detailed information on these data.

Callback Block Used in Conjunction with Indirect Block

When a block using a callback routine is also loaded indirectly there are slight behavior differences. The procedure for loading is:

- 1. Data is loaded into the temporary buffer defined by the `pTempBuffer`.
- 2. The `CALL` to the `pCallBackFunction` is issued.
- 3. After the callback routine returns, if the return value is zero, the memory DMA copies data to the destination

If a block does not fit entirely into the temporary buffer, loading is performed similar to indirect blocks, and the callback function is called after each chunk is loaded into the temporary storage. The `dCbFlags` parameter gives information on the specific iteration.

When a block does not fit entirely into the temporary storage area, the `dCbFlags` tells the callback routine whether it is invoked for the first time (`CBFLAG_FIRST`) or whether it is called the last time (`CBFLAG_FINAL`) for a specific block.

When DMA is invoked to copy the data, it relies on the `pCallbackStruct` structure, not the global `pTempBuffer` and `dTempByteCount` variables. The callback routine can control the source of the memory DMA by altering the content of the `pCallbackStruct` structure, as may be required if the callback routine performs data manipulation such as decompression.

When an indirect block is used, the return value of the callback routine determines whether the DMA transfer occurs. If the value is non-zero, then the transfer does not occur.

Table 34-8: Flags

| Flag           | Required Value |   |
|----------------|----------------|---|
| BFLAG_CALLBACK | Y              | 1 |

## Quick Boot Block

Quick Blocks are only processed for a full boot. In some booting scenarios, not all memories need to be re-initialized. For example, in a wake-up from hibernate state, off-chip SRAM may not be impacted if it is powered while the processor is in a hibernate state. Dynamic RAM may also not be impacted if it was put into a self-refresh mode before the processor powered down.

The boot kernel uses the following parameters to determine whether or not a quick block should be processed. See the "Global Boot Flow" figure also.

- The `SYSCR` register is read to determine what kind of boot is expected from the boot kernel. The `WURESET` bit is compared against other reset bits to distinguish between cold boot and warm boot situations and to identify wake-up from hibernate situations.
- The `BCODE` bit field in the `SYSCR` register can overrule the native decision of the boot kernel for a software boot.
- The `BFLAG_WAKEUP` bit in the `dFlag` word of the `STRUCT_ROM_BOOT_CONFIG` structure indicates that the final decision was to perform a quick boot. If the boot kernel is called from the application, then the application can control the boot kernel behavior by setting the `BFLAG_WAKEUP` flag accordingly.
- The `BFLAG_QUICKBOOT` flag in the block code word of the block header controls whether the current block is ignored for quick boot.

**Table 34-9:** Flags

| Flag                         | Required Value |   |
|------------------------------|----------------|---|
| <code>BFLAG_QUICKBOOT</code> | Y              | 1 |

## Save Block

A save block saves the payload of the block to off-chip memory. This flag is not used by the on-chip boot kernel

**Table 34-10:** Flags

| Flag                    | Required Value |   |
|-------------------------|----------------|---|
| <code>BFLAG_SAVE</code> | Y              | 1 |

## Forward Block

A forward block is similar to a normal block except that the payload is written to a specified peripheral rather than loaded to memory. Rather than specifying a target address, a forward port is defined and the

data is forwarded accordingly. This feature can enable multiple processors in a system to be booted from the same source. This can be done in any hierarchical way using daisy chaining via supported peripherals. An entire boot stream can be contained in the payload of a block, and that entire stream can be forwarded to a peripheral.

The processor supports forwarding to the SPI and link ports. Any peripheral must first be initialized before any forward block that is using that peripheral is processed. This is accomplished by using the boot kernel's *Forward Config* (FUNC\_ROM\_FWDCFG) function. See the ROM API for more information on this function. The forward configuration function takes as arguments the specific peripheral to be initialized and performs all the required initialization for that peripheral to enable forwarding.

As mentioned earlier, the target address for forward blocks is a forward port rather than target address. The details of this parameter are peripheral specific. For purposes of forwarding, the TARGET\_ADDRESS field in the block header is referred to as dForwardPort.

Forwarding to SPI

Figure 34-4: SPI dForward Port

The *SPI dForward Port* figure describes the various options available in the `dForwardPort` field for SPI block forwarding.

- For forwarding a boot stream to the SPI port, the `BFWD_DEVICE` field in the `dForwardPort` argument needs to be set to `BFWD_DEVICE_SPI`. The device source can be SPI0 or SPI1, depending on the `BFWD_DEVENUM` field.
- When using both device sources, the Forward Config API routine needs to be called twice.
- A source device can serve multiple SPI slave devices and is selectable using the SPI SSELx signal (set in `BFWD_CHANNEL`). If multiple slave devices are connected to the FCS signal (`SPI_RDY`), a TBD pull-down resistor is absolutely required as the SPI slave devices have the `SPI_CTL.ODM` bit set to avoid conflicts on the SPI bus. The `BFWD_SPI_FCPL` register must be TBD (set/cleared).

The `BFWD_SPI_MCODE` field is used to choose the I/O mode; 0, 1, or 2 choose single-bit, dual-bit, or quad-bit mode. Setting `BFWD_SPI_MCODE` to 0, 1, or 2 also enables the automode detection command in front of the boot stream. See SPI Slave Boot specification for further details.

The `BFWD_SPI_MCODE3` register selects the legacy single-bit mode without sending any automode detection command. The `BFWD_SPI_CLOCK` register is required to set the lower 8 bits of the BAUD field in the `SPI_CLOCK` divider register. The upper 8 bits of the BAUD field are set to 0. The other fields are used to directly manipulate specific SPI Control register settings.

## Forwarding to the Link Ports

`dForwardPort`: `dForwardPort` Argument - RW

**Figure 34-5:** Link Port `dForward Port`

The link port dForward port describes the various options available in the dForwardPort field for link port block forwarding. For forwarding data to any of the link ports, the BFWD\_DEVICE field in the dForwardPort argument needs to be set to BFWD\_DEVICE\_LPT. The BFWD\_DEVENUM field selects whether data is forwarded to LPT0, LPT1, LPT2 or LPT3. Data can be forwarded to multiple link ports. However, the Forward Config routine needs to be called for each link port separately. The only programming option for Forwarding through link ports is the BFWD\_SPI\_CLOCK field in the dForwardPort argument. The Forward Config routines copies the value into the respective LPx\_DIV register. The Forward Callback routine does not evaluate this bit field. The Forward Config routine automatically sets the pin muxing as required and initializes the link port peripheral.

**Table 34-11:** Flags

| Flag           | Required Value |                                                            |
|----------------|----------------|------------------------------------------------------------|
| BFLAG_FORWARD  | Y              | 1                                                          |
| BFLAG_INDIRECT | Y              | 1                                                          |
| TARGET_ADDRESS | Y              | Contents of the peripheral specific dForwardPort parameter |

## Multi-DXE Boot Streams

This section describes Multi-DXE boot loader streams.

As seen by the elfloader, a boot stream is always generated from a DXE file. It is therefore common to refer to multi-DXE or multi-application booting. When the elfloader utility accepts multiple DXE files on its command line, it generates a contiguous boot image by default. The second boot stream is appended immediately to the first one. Since the utility updates the ARGUMENT field of all BFLAG\_FIRST blocks, the ARGUMENT field of a BFLAG\_FIRST block is called the next-DXE pointer.

The next-DXE pointer of the first DXE boot stream points relatively to the start address of the second DXE boot stream. A multi-DXE boot image can be seen as a linked list of boot streams. The next-DXE pointer of the last DXE boot stream points relatively to the next free address. This is illustrated by an example shown in the [Multi-DXE Boot Stream Example](#) figure.

**Figure 34-6:** Multi-DXE Boot Stream Example

The *Multi-DXE Direct Code Execution Example* figure shows a linked list of initial block headers that instruct the boot kernel to terminate immediately and to start code execution at the address provided by the target address field of the individual blocks. There is nothing in the boot ROM that prevents multi-DXE applications from mixing regular boot streams and direct code execution blocks.

Figure 34-7: Multi-DXE Direct Code Execution Example

Single-Block Boot Streams

This section describes how to bypass booting and execute code directly from SDRAM.

The simplest boot stream consists of a single block header and one contiguous block of instructions. When the appropriate flags are set in the block header, the kernel loads the block to the target address, terminates, and begins executing from the target address of the block.

The *Initial Header for Single-Block Stream* table shows an example of a single-block boot stream header settings that can be loaded using any boot mode. The BFLAG\_FIRST and BFLAG\_FINAL flags are both set at the same time and the target address and byte count are determined by the desired location of the application.

Table 34-12: Initial Header for Single-Block Stream

| Field      | Description of Value                      |
|------------|-------------------------------------------|
| BLOCK_CODE | 0xAD000000 XORSUM BFLAG_FINAL BFLAG_FIRST |

**Table 34-12:** Initial Header for Single-Block Stream (Continued)

| Field          | Description of Value                                     |
|----------------|----------------------------------------------------------|
| TARGET_ADDRESS | Start address of block and application code              |
| BYTE_COUNT     | number of bytes in the block                             |
| ARGUMENT       | Functions as next-DXE pointer in multi-DXE boot streams. |

## Direct Code Execution

This section describes how to bypass booting and execute code directly from SDRAM.

Applications may want to avoid long booting times and start code execution directly from flash or SDRAM memory. This feature is called direct code execution.

An initial boot block header is required for the processor to fetch and execute program code from the boot device as early as possible. The safety mechanisms of the block, such as the header signature and the XOR checksum, are used to avoid unpredictable processor behavior when boot memory is not yet being programmed with valid data. Rather than blindly executing code, the boot kernel first executes the preboot routine for system customization, then loads the first block header and checks it for consistency. If the block header is corrupted, the boot kernel goes into a safe idle state and does not start code execution.

If the initial block header check is good, the boot kernel interrogates the block flags. If the block has the BFLAG\_FINAL flag set, the boot kernel immediately terminates and jumps directly to the address stored in the EVT1 register. To cause the boot kernel to customize the EVT1 register in advance, the first block must also have the BFLAG\_FIRST flag set. The target address field is then copied to the EVT1 register. In this way the target address field of the initial block defines the start address of the application.

For example, if BMODE = 1, when the block header described in the Initial Header table is placed at address 0x20000000, the boot kernel is instructed to issue a JUMP command to address 0x20000020.

The development tools must be instructed to link the above block to address 0x20000000 and the application code to address 0x20000020. An example shown in "Direct Code Execution" illustrates how this is accomplished using the tools suite.

**Table 34-13:** Initial Header

| Field          | Value      | Comments                                                                |
|----------------|------------|-------------------------------------------------------------------------|
| BLOCK_CODE     | 0xAD7BD006 | 0xAD000000 XORSUM BFLAG_FINAL BFLAG_FIRST BFLAG_IGNORE (MDMACODE & 0x6) |
| TARGET_ADDRESS | 0x20000020 | Start address of application code                                       |

**Table 34-13:** Initial Header (Continued)

| Field      | Value      | Comments                                                                                                                  |
|------------|------------|---------------------------------------------------------------------------------------------------------------------------|
| BYTE_COUNT | 0x00000010 | Ignores 16 bytes to provide space for control data such as version code and build data. This is optional and can be zero. |
| ARGUMENT   | 0x00000010 | Functions as next-DXE pointer in multi-DXE boot streams.                                                                  |

## Boot Modes

The boot kernel provides a variety of built-in support, such as call modes, for booting to various peripherals. The [Booting Modes](#) table describes the various boot modes.

In *slave* boot modes, the processor functions as a slave to any host device. In these modes the processor RESET input is usually controlled by the host device. Typically the host sets RESET and waits until the processor is ready to boot, depending on the peripheral being used, and transmits the boot stream data to the processor.

In a *master* boot mode, the processor controls the peripheral and indicates to the peripheral when to transmit the boot stream data.

**Table 34-14:** Booting Modes

| BMODE[2:0] | Boot Source      | Description                                                                          |
|------------|------------------|--------------------------------------------------------------------------------------|
| 000        | No Boot -idle    | The processor does not boot. Rather the boot kernel executes and IDLE instruction.   |
| 001        | Memory boot      | Boot from an address in memory, by default this is the start address of flash memory |
| 010        | RSI master boot  | Boot through the Removable Storage Interface (RSI) peripheral configure as a slave   |
| 011        | SPI0 master boot | Boot through the Serial Port Interface (SPI0) peripheral configured as a slave       |
| 100        | SPI0 slave boot  | Boot through the SPI0 peripheral configured as a master                              |
| 101        | reserved         | reserved                                                                             |
| 110        | LP0 slave boot   | Boot through the Link Port (LP0) peripheral configured as a master                   |
| 111        | UART0 slave boot | Boot through the UART0 peripheral configured as a master                             |

## No-Boot Mode

When the `BMODE` pins are all tied low (`BMODE=0000`), the processor does not boot. Instead it throws an emulation interrupt followed by an idle instruction. The purpose of this mode is to bring the processor up to a clean state from any unwanted state that may have been caused by incorrect programming of the boot source memory.

When connecting to an emulator and starting a debug session, the processor uses the emulation interrupt to wake up the processor and it can be debugged in the normal manner.

## Memory Boot Mode

The memory booting modes are intended for booting from flash, EEPROM, or any memory-mapped devices. Although this is a single `BMODE` setting, there are various configurations described in the MDMA Codes table.

By default the boot kernel does not alter any `EBIO` registers. Therefore, traditional asynchronous memory is assumed and maximum wait states are applied. Once the processor boots, the boot kernel loads an initial burst of 160-bit words, and interrogates the loaded `MDMACODE`. `MDMACODE` is the specialized version of the `BCODE` field defined in a generic block header.

The `MDMACODE` is filled by the `elfloader` utility based on boot mode, `-width` and `-dmawidth` settings. See the Loader and Utility Manual for more details.

**NOTE:** If the NOR flash device has been put into burst or page mode, it must be programmed back to the standard mode before the processor is reset. If the processor can reset itself without software control (via watchdog or double-fault error) a mechanism must be installed that also resets the flash device back to its default mode along with the processor.

Hardware configurations for the individual modes are shown in the 8/16-bit Flash Interconnection figure. The chip select is always controlled by the `ASMO` strobe. Some flash devices provide write protection mechanisms, which can be activated during the power-up and reset cycles on the processor. In the absence of

such mechanisms, a pull-up resistor on the AMS0 pin prevents the chip select from floating when the state of the processor is unknown.

**Figure 34-8:** 8-bit Flash Interconnection

**Figure 34-9:** 16-bit Flash Interconnection

**Table 34-15:** MDMA Codes

| MDMACODE | Word Width | Source Modify | Purpose                                                |
|----------|------------|---------------|--------------------------------------------------------|
| 0x0      |            |               | reserved, protects against legacy 10-byte boot streams |
| 0x1      | 8 bits     | 1             | 8-bit flash on 8-bit SMC/EBIU                          |
| 0x2      | 8 bits     | 2             | 8-bit flash on 16-bit SMC/EBIU                         |
| 0x3      | 8 bits     | 4             | 8-bit flash on 32-bit SMC/EBIU                         |
| 0x4      | 8 bits     | 8             | reserved - not supported                               |
| 0x5      | 8 bits     | 16            | reserved - not supported                               |
| 0x6      | 16 bits    | 2             | 16-bit flash on 16-bit SMC/EBIU                        |
| 0x7      | 16 bits    | 4             | 16-bit flash on 32-bit SMC/EBIU                        |
| 0x8      | 16 bits    | 8             | reserved - not supported                               |
| 0x9      | 16 bits    | 16            | reserved - not supported                               |
| 0xA      | 32 bits    | 4             | 32-bit flash on 32-bit SMC/EBIU                        |
| 0xB      | 32 bits    | 8             | reserved - not supported                               |
| 0xC      | 32 bits    | 16            | reserved - not supported                               |

**Table 34-15:** MDMA Codes (Continued)

| MDMACODE | Word Width | Source Modify | Purpose                  |
|----------|------------|---------------|--------------------------|
| 0xD      | 64 bits    | 8             | reserved - not supported |
| 0xE      | 64 bits    | 16            | reserved - not supported |
| 0xF      | 128 bits   | 16            | reserved - not supported |

To illustrate how the MDMACODE effects reading memory, consider eight contiguous bytes A through H in the following scenarios. In the first, a 16-bit device is used on the 16-bit SMC, stored as BA, DC, FE, HG.

**Table 34-16:** MDMACODE effect on memory read

| MDMACODE | Read by kernel as      |
|----------|------------------------|
| 0x1      | A, B, C, D, E, F, G, H |
| 0x6      | BA, DC, FE, HG         |
| 0xA      | DCBA, HGFE             |

## Padding Memory

To ensure data is read properly for the specific configuration, it may be necessary to pad data when storing it in the device. A few examples follow.

If an 8-bit flash device is connected to the 16-bit SMC only the lower byte is populated and the upper byte needs to be ignored by the kernel. This is ensured by setting MDMACODE = 0x2. To use a 16-bit flash to simulate this, the upper byte is usually zero padded. The 16-bit flash device is programmed with the content of 0A, 0B, 0C, 0D, 0E, 0F, 0G, 0H.

Similarly, setting MDMACODE = 0x3 supports 8-bit flash on 32-bit SMC. This case can be simulated by connecting a 32-bit flash to a 32-bit SMC, or by connecting a 16-bit flash to a 16-bit SMC. In either case, the flash is programmed with three padding bytes per data byte: 000A, 000B, 000C, 000D, 000E, 000F, 000G, 000H.

Finally, setting MDMACODE=0x7 supports 16-bit flash on a 32-bit SMC. This case can also be simulated by connecting a 32-bit flash to a 32-bit SMC, or by connecting a 16-bit flash to a 16-bit SMC. This time 16-bit padding is required per 16-bit data byte: 00BA, 00DC, 00FE, 00HG.

## Auto Detection

An automatic configuration detection is provided that uses the first nibble of the boot stream (MDMACODE field). The boot code requests the initial eight bytes by 32-bit MDMA, inspects the MDMACODE and then adjusts

to 8-bit or 16-bit MDMA operation as needed. During this detection sequence, external memory addresses are fetched sequentially; alternatively a sequential device (such as a FIFO) can be connected.

When the Boot Routine API function is called at run time, the same auto-detection is performed. If auto-detection is not wanted, it can be suppressed by the `BCMD_NOAUTO` switch. See the Run-time API section for details. It is important to understand the `BCMD_NOAUTO` enables the `MDMACODE` to be changed at runtime. If data is arranged on the same flash device in different ways, its perfectly valid to rotate though `MDMACODE` settings 0x01, 0x6 and 0xA, because all three `MDMACODE`s can operate on the same physical arrangement and the same flash image. However, setting `MDMACODE` to 0x2, 0x3 and 0x7 requires a very specific format and are therefore not interchangeable.

## Default Static Memory Controller (SMC) settings

In Memory Boot mode, the boot kernel attempts to boot from the ASYNC Bank 0 Memory Space. Bank 1, Bank 2 and Bank 3 are not initialized. If required, they can be initialized by `initcode`. The SMC registers are set by default as described in the Default SMC Settings table.

**Table 34-17:** Default SMC Settings

| Register Bit       | Value | Note                                |
|--------------------|-------|-------------------------------------|
| SMC_B0CTL_EN       | 1     | enable bank AMS0                    |
| SMC_B0CTL_MODE     | 0     | normal asynchronous mode            |
| SMC_B0CTL_RDYEN    | 1     | enable ARDY                         |
| SMC_B0CTL_RDYPOL   | 1     | ARDY is active high                 |
| SMC_B0CTL_RDYABTEN | 0     | disable ARDY abort counter          |
| SMC_B0CTL_PGSZ     | 0     | 4-byte page size                    |
| SMC_B0CTL_BLK      | 1     | NOR clock = $SCLKA/2$               |
| SMC_B0CTL_BYTPE    | 0     | wrap bursts                         |
| SMC_B0CTL_SELCTRL  | 0     | normal AMS0 strobe                  |
| SMC_B0TIM_WST      | 7     | $7 \times 8\text{ns} = 56\text{ns}$ |
| SMC_B0TIM_WHT      | 7     | $7 \times 8\text{ns} = 56\text{ns}$ |
| SMC_B0TIM_WAT      | 9     | $9 \times 8\text{ns} = 72\text{ns}$ |
| SMC_B0TIM_RST      | 7     | $7 \times 8\text{ns} = 56\text{ns}$ |

**Table 34-17:** Default SMC Settings (Continued)

| Register Bit     | Value | Note                                |
|------------------|-------|-------------------------------------|
| SMC_B0TIM_RHT    | 1     | $1 \times 8\text{ns} = 8\text{ns}$  |
| SMC_B0TIM_RAT    | 8     | $8 \times 8\text{ns} = 64\text{ns}$ |
| SMC_B0ETIM_PREST | 1     | $1 \times 8\text{ns} = 8\text{ns}$  |
| SMC_B0ETIM_PREAT | 3     | $3 \times 8\text{ns} = 24\text{ns}$ |
| SMC_B0ETIM_TT    | 2     | $2 \times 8\text{ns} = 16\text{ns}$ |
| SMC_B0ETIM_IT    | 2     | $2 \times 8\text{ns} = 16\text{ns}$ |
| SMC_B0ETIM_PGWS  | 9     | $9 \times 8\text{ns} = 72\text{ns}$ |

## Run-time API

A Memory Boot can be initiated through the Boot Routine API function at run time. Any start address which is divisible by 4 can be specified. The API allows customizations such as booting from a different SMC bank, and disabling auto-detection.

Memory Boot is selected by specifying the `BCMD_DEVICE_MEMORY | BCMD_MEMORY` in the boot command argument. If `BCMD_DEVENUM_0` is specified, the routine extracts from the start address which SMC bank to configure. If, however, `BCMD_DEVENUM_1` is specified, the `BCMD_MEM_SMCBANK` field selects the SMC bank which is configured.

In either case the routine also initializes pin muxing as required unless the `BCMD_NOCFG` flag is specified, which overrules `BCMD_DEVENUM` and `BCMD_MEM_SMCBANK`. If the `BCMD_NOCFG` flag is specified, it is the programs responsibility to configure SMC and pin muxing as required. This is the only way to boot in burst, page or (the so-called) flash mode. The `BCMD_NOCFG` option is useful if a different application (dx) has been booted earlier and the SMC and pin muxing have already been set up.

The `MDMACODE` configuration detection can be suppressed by the `BCMD_NOAUTO` switch. In this case, the desired configuration can be passed through the `BCMD_MODE` bit field. It follows `MDMACODE` through table convention.

## RSI Master Boot Mode

The RSI master boot mode loads a loader stream through the Removable Storage Interface (RSI). After reset or power on, the boot kernel performs auto-detection of the device to determine its type. Device types supported by auto-detection are:

- Secure Digital (SD), low/high capacity, 1/4-bit
- Multi Media Card (MMC), low/high capacity, 1/4-bit
- MMC plus, low/high capacity, 1/4/8-bit
- Embedded MMC (eMMC) low/high capacity, 1/4/8-bit as aaaaa

The boot kernel optimizes clock settings based on an RSICODE provided in the first nibble of the first block (defined as BCODE code in the block header definition). When booting from RSI, pagemode is used to load data. This provides better support for block based devices (most RSI devices are block based).

Every block loaded in RSI boot mode is loaded implicitly as an indirect, callback block. A callback routine is not required, but may be useful. An indirect callback block causes the boot kernel to first load pages to a temporary buffer where a callback routing may be used to load the data to a file system or perform other modifications. If no callback routine is specified the block is simply loaded. The Boot Routine API allows more advanced customization for booting from RSI. Using this API, auto-detection can be disabled and the device can be specified and configured manually.

## PageMode Customization

Devices attached to the RSI peripheral are typically block based devices. The boot kernel has built-in support for booting from this type of block based device called pagemode. In pagemode data is loaded by fixed block sizes. The default page size used is 512 bytes. This value can be changed using the initcode routine to modify the `dTempByteCount` parameter in the `struct STRUCT_ROM_BOOT_CONFIG` structure. Refer to pagemode and Init Block for details on making these changes.

## Callback Customization

Frequently, devices connected to the RSI have filesystem implemented on them. The motivation for implicitly enabling a callback for every block is to ease implementation on such systems. By default the callback routine is empty and simply returns a value of zero. The standard procedure for loading and registering a callback function should be used early in the stream. See the callback block section for more detailed information on performing this customization.

## RSI Code

When performing auto-detection, the first block of data is loaded using the bus width defined by the RSICODE. The RSI code is defined by the first block in the boot stream and is located in the block header where BCODE is defined in a generic block code, (see Block Code). The boot kernel then reconfigures the RSI peripheral according to the value detected in the RSICODE.

**Table 34-18:** RSI Code

| RSICODE | uwFlag   | ubBusWidth | ubRsiClk | ubRsiClk High Speed | Description                      |
|---------|----------|------------|----------|---------------------|----------------------------------|
| 0       | 0x0000   | 0x00       | 0x3      | N/A                 | 1 bit, regular speed protocol    |
| 1       | 0x0020   | 0x00       | 0x3      | 0x1                 | 1 bit, high speed protocol(1)    |
| 2       | 0x0000   | 0x01       | 0x3      | N/A                 | 4 bit, regular speed protocol    |
| 3       | 0x0020   | 0x01       | 0x3      | 0x1                 | 4 bit, high speed protocol(1)    |
| 4       | 0x0000   | 0x02       | 0x3      | N/A                 | 8 bit, regular speed protocol(2) |
| 5       | 0x0020   | 0x02       | 0x3      | 0x1                 | 8 bit, high speed protocol(1)(2) |
| 6-15    | reserved |            |          |                     |                                  |

## Run-Time API

The RSI Boot mode can also be initiated through the Boot Routine API. The boot routine allows for further customization by modifying values in the `dBootCommand` parameter. This can be useful when it is necessary to bypass auto-detection of the device.

**dBootCommand: dBootCommand Parameter for RSI Master Boot Mode - RW**

**Figure 34-10: dBootCommand for RSI Boot**

When `BMC_NOAUTO` is set, the RSI clock divider is taken from the `BCM_RSI_CLK` field. The device type of the attached device is taken from the `BCMD_CHANEL` field and the access type is taken from the `ACCESS` field. The `RSICODE` field is still applicable and processed in order to set the bus width and speed protocol to use.

**NOTE:** The device identification phase is not executed. Therefore the attached device must be in the transfer state before executing the API call.

In order to communicate with an attached device that is in the transfer state, the RCA of the device is required. For example, `CMD13` reads the card's status in the event the switch command was executed to change the bus width or timings of the device. The card's RCA is therefore required to be written to the `uwRca` field of the RSI structure via the use of the hook function that can be passed to the boot kernel via the API. Failure to do so may lead to a boot failure

For MMC devices that support boot blocks, the contents of byte 179 of the Extended CSD register should be written to the `ubBootPartByte` of the RSI structure. This should be preformed via the hook function. In particular bits [7:3] should be set accordingly. Bits [2:0] may be modified by the boot code depending on the device passed via the `BCMD_RSI_TYPE` field of `dBootCommand`.

The boot kernel uses a byte write operation to write byte 179 of the Extended CSD register which impacts the non-volatile bits of the byte. When `BCMD_NOAUTO` is set, the Extended CSD register is not read which speeds up the process. Set the non-volatile bits accordingly. Programs may do this by reading the Extended CSD register at some point in the application and passing in byte 179 accordingly.

## Notes on eMMC

The boot kernel includes support to handle boot partitions on eMMC devices. The extended CSD register is a register on the eMMC device with a byte containing boot partition information. The boot kernel uses this byte to activate the required partition accordingly to then get the boot stream. While the boot partition may be small, it may be sufficient to store something like UBOOT in loader stream format. UBOOT can be loaded from this special boot partition and then it can continue to boot having knowledge of the main file system are of the eMMC.

## SPI Master Boot Mode

Describes booting from the Serial Peripheral Interface (SPI).

This SPI Master Boot mode boots from SPI memory connected to the SPI0 interface. 8-bit, 16-bit, 24-bit and 32-bit address words are supported. Standard SPI memory is read using either the standard 0x03 SPI read command or the 0x0B SPI fast read command.

For booting, the SPI memory is connected as shown in [SPI Memory Connections](#)

**Figure 34-11:** SPI Memory Connections

The pull-up resistor on the MISO line is required for automatic device detection. The pull-up resistor on the SEL1 line ensures that the memory is in a known state when the GPIO is in a high-impedance mode such as during reset. A pull-down resistor on the SCK line displays cleaner oscilloscope plots during debugging.

For SPI master boot the `SPE`, `MSTR` and `SZ` bits are set in the `SPI0_CTL` register. The `TIMOD=2` bits enable the receive DMA mode. Clearing both the `CPOL` and `CPHA` bits results in SPI mode 0. The boot kernel does not allow SPI0 hardware to control the `SEL1` pin. Instead, this pin is toggled in GPIO mode by software.

Initcodes are allowed to manipulate the `uwSsel` variable in the [STRUCT\\_ROM\\_BOOT\\_CONFIG](#) structure to extend the boot mechanism to a second SPI memory connected to another GPIO pin.

## SPI Device Detection Routine

Since `BMODE = 011` supports booting from various SPI memories, the boot kernel automatically detects what type of memory is connected. To determine whether the SPI memory device requires an 8, 16, 24 or 32-bit addressing scheme, the boot kernel performs a device detection sequence prior to booting. The MISO signal requires a pull-up resistor, since the routine relies on the fact that memories do not drive their data outputs unless the right number of address bytes are received.

Initially, the boot kernel transmits a read command (either `0x03` or `0x0B`) on the MOSI line, which is immediately followed by two zero bytes. Once the transmission is finished, the boot kernel interrogates the data received on the MISO line. If it does not equal `0xFF`, the valid byte (`0x1-0xE` in the lower nibble) tells the boot code whether the memory device requires 8, 16, 24, 32 address bits. This is referred to as the `SPIMCODE`. The boot kernel has the following settings according to the [SPIMCODE Descriptions](#) table.

If the received value equals `0xFF`, it is assumed that the memory device has not driven its data output and that the `0xFF` value is due to the pull-up resistor. Thus, another zero byte is transmitted and the received data is tested again.

If the value still equals `0xFF`, device detection continues. Device detection aborts immediately if a byte different than `0xFF` is received. The boot kernel continues with normal boot operation and it reissues a read command to re read from address 0. The first block header is loaded by two read sequences, further block headers and block payload fields are loaded by separate read sequences.

Figure [SPI Device Detection Principle](#) illustrates how individual devices behave.

## Run-time API

The Boot Routine API function can be used to initiate a boot through the SPI device. Using the API, further customizations can be made such as selecting a device other than SPI0, or disabling automated device initialization and pin muxing. Refer to the specific flags in the [dBootCommand for RSI Boot](#) parameter.

**dBootCommand: dBootCommand Parameter for SPI Master Boot Mode - RW**

**Figure 34-13: dBootCommand for RSI Boot**

## SPI Slave Boot Mode

Describes booting from the Serial Peripheral Interface (SPI) with the processor as a slave.

When using SPI slave mode boot, the processor consumes boot data from an external SPI host device. This mode supports single, dual, and quad-bit modes. The boot kernel always starts in single bit mode and can be changed using the appropriate command. The hardware configuration for the modes is shown in the following figures. As in all slave boot modes, the host device controls the Blackfin processor's RESET input.

**Figure 34-14:** Connection Between Host (SPI Master) and Processor (SPI Slave)

**Figure 34-15:** Connection Between Host (SPI Master) and Processor (SPI Slave) DIOM

**Figure 34-16:** Connection Between Host (SPI Master) and Processor (SPI Slave) QSPI

The host drives the SPI clock and is responsible for timing. The host must provide an active-low chip select signal that connects to the SPI0 SS input of the Blackfin processor. It can toggle with each byte transferred or remain low during the entire procedure. 8-bit data is expected and 16-bit mode is not supported.

In SPI slave boot mode, the boot kernel sets the CPHA bit and clears the CPOL bit in the SPI\_CTL register. Therefore the MISO pin is latched on the falling edge of the MOSI pin. For details see "SPI Compatible Port Controllers" in the Processor Hardware Reference.

The SPI slave processor detects the correct bit mode from the host SPI device by reading the first byte sent, defined as the SPICMD. The following table describes the available codes. If the host starts in dual or quad-bit mode, additional bytes need to be sent to transmit the correct code.

**Table 34-20:** SPICMD Descriptions

| SPICMD                                | Description             |
|---------------------------------------|-------------------------|
| Starting in Single bit Mode           |                         |
| 0x3                                   | keep single-bit mode    |
| 0x7                                   | switch to dual-bit mode |
| 0xB                                   | switch to quad-bit mode |
| If host device starts in DIOM or QSPI |                         |
| 0xAA,0xBF                             | switch to dual-bit mode |
| 0xEE,0xEE,0xFE,0xFF                   | switch to quad-bit mode |

In SPI slave boot mode, SPI\_RDY functionality is critical. The SPI\_RDY output is used for back pressure and requires a pull-up resistor. When high, the resistor shown in Figure programs SPI\_RDY to hold off the host. SPI\_RDY holds the host off while the Blackfin processor is in reset or executing the preboot. Once SPI\_RDY turns inactive, the host can send boot data. The SPI module does not provide very large receive FIFOs, so the host must test the HWAIT signal for every byte. Figure [SPI Program Flow on the Host Side](#) illustrates the required program flow on the host side.

**Figure 34-17:** SPI Program Flow on the Host Side

Run-Time API

The SPI Slave Boot mode can be called through the Boot Routine API function at run time. Initiating a boot through the run-time API allows for additional customization such as disabling automatic device configuration or specifying a different SPI device other than SPI0.

When BFROM\_BCMD\_NOCFG flag is specified, it is necessary to program pin muxing and other SPI configuration as required, while keeping the SPI\_CTL.EN bit cleared.

The automode detection can be suppressed by the BFROM\_BCMD\_NOAUTO switch. In that case, the desired configuration must be passed through the BFROM\_BCMD\_SPI\_CODE bit field, even if the BFROM\_BCMD\_NOCFG flag is set.

Figure *dBootCommand* describes the fields possible for customization through the dBootCmd parameter.

dBootCommand: dBootCommand Parameter for SPI Slave Boot Mode - RW

Figure 34-18: dBootCommand

Link Port Slave Boot Mode

Describes booting from the Link Port with the processor as a slave

Link port boot is a slave boot mode in which the processor receives boot data from an external link port master through link port 0. The link port is configured for receive mode and all transfers from the link port to memory are performed under the control of DMA. The maximum supported operating frequency of the Link Port is 66MHz for which the master boot source is responsible for deriving the clock frequency. The link port receiver operates at an asynchronous frequency up to the maximum supported operating frequency.

The link port protocol supports a means of generating link port transmit and receive service requests. The transmit service request is generated on the processor to transmit the data by the receiver driving the `LACKx` signal high when the transmitter is disabled. The receive service request is generated on a receiver when it is disabled. This is initiated by the transmitter driving the `LCLKx` signal high.

As transmitter and receivers may be enabled at different times external pull-down resistors are required on both the `LCLKx` and `LACKx` signals in order to eliminate any false service request assertions.

The link port slave boot mode initialization phase waits for the receive service request before passing control back to the main kernel. Once this initial receive service request has been detected the receiving link port is enabled and the boot process completes. At no point prior to boot completion is the receiving link port disabled again. Once the link port is enabled all transfers are controlled by the receive DMA channel. The Load function for the link port Receive Boot mode may therefore simply point to the peripheral DMA routine of the main kernel in a similar way to the SPI slave boot mode.

## **Run-time API**

The Boot Routine API function can be used to load a boot stream through the link port peripheral. Using this API the specific LP device may also be chosen, otherwise only link port0 is assumed. See the kernel API section for specifics on how to use this function.

### dBootCommand: dBootCommand Parameter for Linkport Boot Mode - RW

**Figure 34-19:** dBootCommand for Link Port Boot

## UART Slave Boot Mode

When using UART slave mode boot, the processor receives boot data from a UART host device connected to the UART interface. The device connected to UART0 is initially detected using an autobaud detection sequence. After finishing the UART slave boot process, all control and status registers of the used resources are restored.

Further customization, such as disabling autobaud detection, and changing the device, can be done using the Boot Routine API.

During the boot operation, the host device usually relies on the **RTS** output of the UART device. At boot time the processor does not evaluate RTS signals driven by host. Since the RTS is in a high impedance state when the processor is in reset, or while executing a preboot, an external pull-up resistor to **VDDEXT** is recommended. The Connection Between Host and Processor figure shows the interconnection required for booting. The figure does not show physical line drivers and level shifters that are typically required to meet the individual UART-compatible standards.

**Figure 34-20:** Connection Between Host and Processor

When the UART is enabled, the RTS goes immediately low, encouraging the host to send the first boot stream data as shown in the figure. In the case of half-duplex UART connections, this must be avoided. The host should wait until it has received the four bytes from the slave processor, before sending any data.

**Figure 34-21:** Host relying on RTS

When the boot kernel is processing fill or initcode blocks, it might require additional processing time and needs to hold the host off from sending more data. This is signaled using the RTS output.

The figure above shows RTS timing in case an extended initcode routine executes. Since code execution is distracting from the data loading, the host device has to be prevented from sending more data. The timing of the RTS depends on the state of the RFRT bit in the UART Control register (UART\_CTL). This bit is cleared in case of the UART Slave Boot mode and RTS is deasserted when the UART receive FIFO contains 4 or more data words and another start bit is detected.

## Autobaud Detection

The kernel supports autobaud detection using the '@' character as data. The host is expected to have its clock set to rate supported in the UART

To determine the bit rate when performing the autobaud:

1. the boot kernel expects an '@' character (0x40, eight bits data, one start bit, one stop bit, no parity bit) on the UART RXD input.
2. The EDB0 and UART\_CLK register is cleared.
3. The boot kernel acknowledges, and the host then downloads the boot stream. The acknowledgment consists of four bytes: 0xBF, UART\_CLK[15:8], UART\_CLK[7:0], 0x00.

4. The host is requested to not send further bytes until it has received the complete acknowledge string.
5. Once the 0x00 byte has been received, the host can send the entire boot stream.

The host should know the total byte count of the boot stream, but it is not required to have any knowledge about the content of the boot stream.

**Figure 34-22:** UART Autobaud Detection Waveform

The UART Autobaud Detection Waveform figure provides timing information for UART booting. After the bit rate is known, the UART is enabled and the kernel transmits four bytes.

## Run-time API

The UART Slave Boot mode can be called through the Boot Routine API function at run time. The run-time API allows for additional customization. both autobaud detection and device configuration can be disabled, and a device other than the default, UART0, may be specified.

If `BFROM_BCMD_NOCFG` flag is specified, it is the programs responsibility to configure pin muxing as required.

Autobaud detection can be suppressed using the `BFROM_BCMD_NOAUTO` switch. In this case, the desired configuration can be passed through the `BFROM_BCMD_UART_CLK` bit field. If the `BFROM_BCMD_UART_CLK` bit field is zero, `UART_CLK` finally is evaluated. If the reset value is detected, the default error routine of the boot kernel is called and the booting process is aborted. Otherwise the value in `UART_CLK` remains untouched.

The `dBootCommand` figure shows each of the available fields in the `dBootCommand` parameter in the Boot Routine API function.

dBootCommand: dBootCommand Parameter for UART Slave Boot Mode - RW

Figure 34-23: dBootCommand

# Boot Programming Model

This section describes the programming model for booting the processor. The programming model includes booting functions, API calls, and data structures.

## Load Functions

All boot modes are processed by a common boot kernel algorithm. The load function point is exposed by the kernel to allow more complete customization of the booting process. The major customization is done by a subroutine that must be registered to the pLoadFunction pointer in the [STRUCT\\_ROM\\_BOOT\\_CONFIG](#) structure. Its simple prototype is as follows.

```
void LoadFunction (STRUCT\_ROM\_BOOT\_CONFIG* pBootStruct);
```

For some scenarios some of the flags in the dFlags word of the [STRUCT\\_ROM\\_BOOT\\_CONFIG](#) structure, such as BFLAG\_PERIPHERAL and BFLAG\_SLAVE, slightly modify the boot kernel algorithm.

The boot ROM contains several load functions. One performs a memory DMA for memory boot, another performs a peripheral DMA. The first is reused for fill operations and indirect booting as well.

In second-stage boot schemes, programs can create customized load functions or reuse the originals and modify the `pDmaControlRegister`, `pControlRegister` and `nControlValue` values in the `STRUCT_ROM_BOOT_CONFIG` structure. The `pDmaControlRegister` points to the `DMAx_CONFIG` or `MDMA_Dx_CONFIG` registers. When `BFLAG_SLAVE` flag is not set, the `pControlRegister` and `dControlValue` variables instruct the peripheral DMA routine to write the control value to the control register every time the DMA is started.

Custom load functions must meet the following requirements.

- Protect against `dByteCount` values of zero
- Multiple DMA work units are required if the `dByteCount` value is greater than 65536
- The `pSource` and `pDestination` pointers must be properly updated

In slave boot modes, the boot kernel uses the address of the `dArgument` field in the `pHeader` block as the destination for the required dummy DMA's when payload data is consumed from `BFLAG_IGNORE` blocks. If the load function requires access to the block's `ARGUMENT` word, it should be read early in the function.

## Page Mode

For the benefit of page oriented boot source devices such as RSI, the boot kernel provides support for page operations. Page mode optimizes memory reads for block organized devices by always reading a page, rather than reading data on demand. The same temporary buffer used by the indirect blocks is used in page mode. The size of the buffer is defined by the `dTempByteCount` variable in the `STRUCT_ROM_BOOT_CONFIG` structure. The page size of the physical source device is defined by the `dPageByteCount` variable.

The `pTempSource` variable points to the source address of the data that is currently in the temp buffer. This variable is an internal variable of the boot kernel. However, at any time programs can set this variable to -1 to force the kernel to re fetch source data into the temp buffer. The following items also pertain to Page-mode.

- `dPageByteCount` must be a power-of-2 value (default is 4)
- `dTempByteCount` must be the same as or a multiple of `dPageByteCount` (default is 512)
- `pTempBuffer` does not have special alignment requirements. However, alignment of 32 may speed up DMA operations.
- In page mode, both block payload data and block headers are loaded through the same mechanism.

## Changing Settings at Run Time

Programs can change the `pTempBuffer`, `dTempByteCount`, and `dPageByteCount` variables at any time, even within `initcodes` or `callbacks`. Whenever the settings change the kernel continues to operate on the

old settings until the content of the former temporary buffer has been entirely processed. The new settings only become active for the next load operation. The kernel can be forced to immediately switch to the new settings by setting `pTempSource` to a value of -1. Note that doing so requires the kernel to re fetch data that had been loaded earlier. Under normal conditions `pTempSource` should not be altered.

The [Initcode Routine](#) example illustrates on how page mode can be activated in any boot mode. Think of SPI master mode that has significant overhead when fetching data in little chunks, and for block headers or small boot blocks.

procedure initcode (BOOT\_CONFIG config)

```
# The config input is the boot config datastructure
# change PLL and initialize DDR controller first */
initPLL()
# enable page mode operation
set config.dFlags.BITM_ROM_BFLAG_PAGEMODE to true;

# set to any unused DDR address,
# make sure it is not overwritten by the boot stream
# ideally pointing to an uninitialized section, such as the stack or heap

    set config.pTempBuffer to 0xABCDABCD;
#update the temp byte count
# pSource points to the current source address
# pNextDxe points to the first address after the DXE
set config.dTempByteCount to config.pNextDxe - config.pSource
```

**Figure 34-24:** Initcode Routine Pseudo-Code

## CRC32 Protection

This section describes the CRC32 Protection provisions

The boot kernel provides mechanisms to allow each block to be verified using a 32-bit CRC. To enable this feature, use the kernel initcode routine, `rom_Crc32Initcode`. An init block that provides this function can be created as the target address, and the ARGUMENT field containing the CRC32 checksum polynomial. Once this function is called, CRC verification is enabled for all blocks except forward, ignore, and first blocks. See the Boot Kernel API documentation for the specifics of this Initcode function.

## Error Handler

This section describes how to customize the error handler

While the default handler puts the processor into idle mode, an initcode routine can register a customized error function by overwriting the error function pointer to create a customized error handler. The expected prototype is:

```
void ErrorFunction(STRUCT_ROM_BOOT_CONFIG* pBootStruct, void *pFailingAddress);
```

Use an Initcode Routine (see *Block Types*) to write the entry address of the error routine to the `pErrorFunction` pointer in the `STRUCT_ROM_BOOT_CONFIG` structure. The error handler has access to the entire boot structure and receives the instruction address that triggered the error.

The default Error Routine performs the following actions in the following order:

1. Issues `EMUEXCPT` instruction
2. Issues `INTR_SOFT3` software interrupt to SEC
3. Toggles `FAULTb` pin
4. Issues `0xDEAD4400` value to former `CHIPID` register (`0xFFC00014`) to halt the simchip simulator
5. Issues an `IDLE` instruction
6. While (CC) loop;
7. Returns (RTS)

## Fault Management

Unless the `RCU_BCODE_NOFAULTS` or `RCU_BCODE_HALT` registers are set, the main routine enables the SEC and configures the following interrupts as faults early in the process:

```
CGU0_ERR, SEC0_ERR, WDOG0_EXP, DMAC_ERR, CRC0_ERR, SOFT3, C0_DBL_FAULT,  
C0_HW_ERR:= SCTL_SEN | SCTL_FEN;
```

For dual-core devices like the ADSP-BF60x family the Core 1 faults are also activated:

```
WDOG1_EXP, C0_BDL_FAULT, C0_HW_ERR:= SCTL_SEN | SCTL_FEN;
```

After memory initialization, the memory protection channels are enabled as faults:

```
L2CTL0_ECC_ERR, INTR_C0_L1_PARITY_ERR and in the dual-core case  
INTR_C1_L1_PARITY_ERR
```

Events on any of these signals during the boot process will assert the `FAULT` and `FAULTb` output pins after a delay. A delay of 256 cycles is used to give the boot code opportunity to self detect the error situation and to execute an `emuexcpt` instruction to alert the emulator if connected.

```
SEC0_FDLY and SEC_FSRDLY are set to 0x100 value. SEC0_FCTL:= FIEN | FOEN | EN;
```

Note that no interrupt is forwarded to either core.

If the boot code detects an error by software, its default error handler sets the INTR\_SOFT3 software interrupt after having executed an EMUEXCPT and before executing an IDLE.

The boot code does not disable the SEC and fault settings on exit so that a safety hole is not introduced when transitioning to user application.

## Callable API Overview

Describes the kernel API available at run-time

The boot code stored in ROM exposes several functions that can be used during run-time or within init-code or callback routines. This section describes the available functions and how they can be used. All functions meet the C runtime calling conventions described in the C/C++ Compiler and Libraries Manual. C prototypes are provided through `cdef_rom.h` header file, and addresses are provided by `thedef_rom.h` header file.

## System Control

The Syscontrol API provides a consistent reliable method to modify the PLL settings of the processor. It is recommended that this is the only method used to modify the PLL settings.

```
uint32_t rom_SysControl(uint32_t dActionFlags, STRUCT_ROM_SYSCTRL *pSysCtrlSettings,  
void *reserved);
```

| Stack Requirements | valid stack (SP, FP dividable by 4) required.                                                                             |

The Syscontrol API provide a normalized method to control setting in the CGU and DDR. The following three types of operations are provided:

- CGU Configuration
- DDR initialization from wakeup event

- CGU and DDR context save and restore operations from the DPM\_RESTOREn registers in order to support entry to hibernate and wakeup from hibernate functionality

Syscontrol does not provide support for:

- Initial configuration of the DDR controller after a power up or reset sequence. The sequence of operations performed for the DDR. Configuration functionality is only compliant with the procedure required in order to restore the DDR configuration in the event of a hibernate/wakeup sequence while the DDR is in the self refresh state.
- Setting the DDR into self refresh mode. The DDR must be set to self refresh mode prior to calling syscontrol in order to save the DDR configuration in preparation of entering hibernate.

Syscontrol has not been designed in such a way that it performs all required operations in a single call. The syscontrol functionality can be broken down into two main categories:

- CGU configuration and limited DDR configuration
- CGU and DDR context save and restore from the DPM\_RESTOREn registers

Syscontrol provides a means of configuring the CGU per user requirements. The CGU\_CTL and CGU\_DIV registers are used to manipulate the various clock frequencies of the system. The [CGU Configuration Capacity](#) table defines the order of the sequences when writing to these two registers.

**Table 34-21:** CGU Configuration Capacity

| CGU_CTL Frequency change | CGU_DIV Frequency change | CGU_DIV_UPDT | CGU_DIV_ALGN | Register Written     |
|--------------------------|--------------------------|--------------|--------------|----------------------|
| No                       | No                       | NA           | NA           | None                 |
| No                       | Yes                      | 1            | 1            | CGU_DIV              |
| Yes                      | No                       | NA           | NA           | CGU_CTL              |
| Yes                      | Yes                      | 0            | 0            | CGU_DIV then CGU_CTL |

*When the CGU\_STAT register indicates that the PLL is disabled then CGU\_DIV\_ALGN is never set.*

CGU and DDR context save and restore operations from the DPM\_RESTOREn registers are enabled with the setting of ROM\_SYSCtrl\_WUA\_EN in the [dActionFlags](#) parameter. When set any CGU or DDR configuration operations are ignored. Therefore any attempt to reconfigure the PLL while this bit is set will not be performed.

The ROM code calls syscontrol itself only when the device is waking up from hibernate. Nevertheless, syscontrol is an important primitive of the boot concept as programs are expected to call syscontrol from within their initcode to speed-up the boot process.

dActionFlags: Syscontrol Action Flags (R/W) - RW

Figure 34-25: dActionFlags

## Boot Kernel

The boot kernel API can be used to implement custom boot modes.

```
void * rom_BootKernel(STRUCT_ROM_BOOT_CONFIG *pBootStruct);
```

### Boot Kernel

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| PP Define?         | FUNC_ROM_BOOTKERNEL                                                                                       |
| Prototype          | void * rom_BootKernel(STRUCT_ROM_BOOT_CONFIG *pBootStruct);                                               |
| Arguments?         | R0: Pointer to pBootStruct                                                                                |
| Return Value       | R0: pSource Pointer to next free source locations Pointer to DXE when invoked by ROM_BFLAG_NEXTDXE switch |
| Stack Requirements | valid stack (SP, FP dividable by 4) required                                                              |

## Boot Routine

The boot routine provides access to boot an application at run-time through a supported peripheral. The boot routine often also provides the ability for further customization over the equivalent boot mode.

```
rom_Boot(...)
```

The Boot Routine can be used for any kind of second-stage boot for supported boot modes. It provides options to boot from any device and any channel, whereas booting directly limits the choice to the default devices and channels. Often any auto-configuration or detection of the device can also be disabled. Each boot mode defines its own dBootCommand, (see individual boot modes for a description of this parameter). The \*pCallHook argument is only needed when BFLAG\_HOOK is set and should otherwise be NULL. The \*pTargetAddress argument is only needed when BFLAG\_DATAREAD is set and should otherwise be NULL.

|           |                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PP Define | FUNC_ROM_BOOT                                                                                                                                                                                                       |
| Prototype | void * rom_Boot( void *pBootStream, dFlags, int32_t dBlockCount, ROM_BOOT_HOOK_FUNC *pCallHook, uint32_t dBootCommand, void *pTargetAddress);                                                                       |
| Arguments | R0: Pointer to Boot Stream (memboot) or Start Address of Boot Stream (SPI boot)<br>R1: dFlags R2: dBlockCount<br>[fp+ 0x14] ROM_BOOT_HOOK_FUNC *pCallHook<br>[fp + 0x18] dBootCommand<br>[fp + 0x1C] pTargetAddress |

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| Return Value       | R0: pSource Pointer to next free source locations Pointer to DXE when invoked by ROM_BFLAG_NEXTDXE switch |
| Stack Requirements | valid stack (SP, FP dividable by 4) required. 0x400 bytes of free stack suggested                         |

## CRC 32 Polynomial

Generates a CRC look-up table using CRC0.

```
bool rom_Crc32Poly(uint32_t ulPolynomial);
```

|                     |                                            |
|---------------------|--------------------------------------------|
| PP Define           | FUNC_ROM_CRC32POLY                         |
| Prototype?          | bool rom_Crc32Poly(uint32_t ulPolynomial); |
| Arguments?          | R0: Polynomial                             |
| Return Value        | 0: on success -1 on failure                |
| Stack Requirements? | none                                       |

## CRC Initcode

The CRC Initcode is called by the bootstream. A respective init block is inserted by the loader utility when invoked by the -crc switch. The CRC Initcode extracts the polynomial from the dArgument field of each block header and calls then the CRC LUT function.

```
void rom_Crc32Initcode( STRUCT_ROM_BOOT_CONFIG *pBootStruct);
```

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| PP Define?         | FUNC_ROM_CRC32INITCODE                                        |
| Prototype?         | void rom_Crc32Initcode( STRUCT_ROM_BOOT_CONFIG *pBootStruct); |
| Arguments?         | R0: Pointer to pBootStruct                                    |
| Return Value?      | none                                                          |
| Stack Requirements | valid stack (SP, FP dividable by 4) required.                 |

## ECC Protection

Protects 64-bit values by 8-bit ECC checksum using Hamming 7264 method. If return values equals ROM\_ECC\_ERROR\_1BIT source data is corrected in place. Cycle count is independent of data and whether correction takes place or not.

```
uint8_t rom_Ecc(u64 *pData, uint8_t bChksum, bool bDecode);
```

|                     |                                                                            |
|---------------------|----------------------------------------------------------------------------|
| PP Define?          | FUNC_ROM_ECC                                                               |
| Prototype?          | uint8_t rom_Ecc(u64 *pData, uint8_t bChksum, bool bDecode);                |
| Arguments           | R0: Pointer to 64-bit data<br>R1: 8-bit checksum<br>R2: 0=encode, 1=decode |
| Return Value?       | R0: 8-bit checksum when bDecode=false error code when dDecode=true         |
| Stack Requirements? | valid stack (SP, FP dividable by 4) required.                              |

**Table 34-22:** bDecode Values

| PP Define          | Description                     |
|--------------------|---------------------------------|
| ROM_ECC_ENCODE     | encode mode                     |
| ROM_ECC_DECODE     | decode mode                     |
|                    |                                 |
| ROM_ECC_ERROR_INVS | invalid syndrome/checksum       |
| ROM_ECC_ERROR_2BIT | uncorrectable 2-bit error       |
| ROM_ECC_ERROR_1BIT | 1-bit error, has been corrected |
| ROM_ECC_ERROR_NONE | no error                        |

## Execute

Resets the core as specified by dCoreId, stores dStartAddress into respective SVECTx registers and the releases the core.

|                    |                                                                        |                        |
|--------------------|------------------------------------------------------------------------|------------------------|
| Name               | Execute                                                                | -                      |
| PP Define          | FUNC_ROM_EXEC                                                          | -                      |
| Prototype          | void rom_Exec( uint32_t dCoreId, void* dStartAddress, void *reserved); | -                      |
| Argument           | R0                                                                     | 0=Core0, 1=Core1       |
| Argument           | R1                                                                     | Pointer to Routine     |
| Argument           | R2                                                                     | reserved, must be zero |
| Return Value       | none                                                                   | -                      |
| Stack Requirements | valid stack (SP, FP dividable by 4) required.                          | -                      |

```
rom_Exec(dCoreID,dStartAddress,0);
```

If dCoreId equals the current core,

- the routine simply issues a call to dStartAddress and returns.
- and the dStartAddress is 0x00000000 or 0xFFFFFFFF, the cycle counter is halted and an idle instruction is executed.

If dCoreId does not equal the current core,

- and the dStartAddress is 0x00000000, the target core is reset and kept in reset.
- and the dStartAddress is 0xFFFFFFFF, the target core vectors to ROM address where the cycle counter is halted and an idle instruction is executed.
- and the dStartAddress is 0xFFFFFFFEE, the target core's SVECTx is used without modification

For safety reasons, the rom\_Exec function does not unlock write access to the RCU0\_SVECT registers. Unlocking and re locking is expected to be managed by the calling function.

|           |                                                                        |
|-----------|------------------------------------------------------------------------|
| PP Define | FUNC_ROM_EXEC                                                          |
| Prototype | void rom_Exec( uint32_t dCoreId, void* dStartAddress, void *reserved); |

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| Arguments          | R0: 0=Core0, 1=Core1, ...<br>R1: Pointer to Routine<br>R2: reserved, must be zero |
| Return Value       | none                                                                              |
| Stack Requirements | valid stack (SP, FP dividable by 4) required.                                     |

## Forward Config

The Forward Config routine is provided initialize the link port and SPI peripherals for using the boot forward feature.

```
uint32_t* rom_ForwardConfig(STRUCT_ROM_BOOT_CONFIG *pBootStruct, uint32_t ulForwardPort);
```

The Forward Config routine initializes the link port and SPI peripherals for using the boot forward feature. This routine must be called from an initcode routine before any forward block can be processed. Refer to documentation on forward block (see [Block Types](#)) documentation for details on pBootStruct as the definition varies for each peripheral.

When called with the BFWD\_CLEANUP flag, the Forward Config routine clears the LPx\_CTL and DMay\_CONFIG registers.

|                     |                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------|
| PP Define?          | FUNC_ROM_FWDCFG                                                                           |
| Prototype           | uint32_t* rom_ForwardConfig(STRUCT_ROM_BOOT_CONFIG *pBootStruct, uint32_t ulForwardPort); |

| 5      | RSICODE look-up table      |

## Mem Compare

Mem Compare compares a specified region of memory against a provide 32-bit reference value. The byte count can be any 32-bit value that is divisible by four, including zero. The DMA channel is disabled after completion, but the DMA status is not cleared so that in the event of an error the DMA can be debugged.

```
bool rom_MemCmp(void *pSrc, uint32_t ulChkVal, uint32_t ulByteCnt);
```

|            |                                                                     |
|------------|---------------------------------------------------------------------|
| PP Define? | FUNC_ROM_MEMCMP                                                     |
| Prototype? | bool rom_MemCmp(void *pSrc, uint32_t ulChkVal, uint32_t ulByteCnt); |

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| Arguments?          | R0: pSrc Source Address<br>R1: Compare Value<br>R2: Byte Count |
| Return Value        | 0: on success -1 on failure                                    |
| Stack Requirements? | none                                                           |

## Memory Copy

The Mem Copy function provides a convenient facility to copy memory using MDMA0 from one location to another. The byte count can be any 32-bit value including zero. The DMA channel is disabled after completion, but the DMA status is not cleared so that in the event of an error the DMA can be debugged.

```
bool rom_MemCpy(void *pDst, void *pSrc, uint32_t ulByteCnt);
```

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| PP Define?          | FUNC_ROM_MEMCPY                                                           |
| Prototype?          | bool rom_MemCpy(void *pDst, void *pSrc, uint32_t ulByteCnt);              |
| Arguments           | R0: pDst Destination Address<br>R1: pSrc Source Address<br>R2: Byte Count |
| Return Value        | 0: on success -1 on failure                                               |
| Stack Requirements? | none                                                                      |

## Memory CRC

MemCRC scrubs memory using MDMA0 and CRC0 and builds a CRC checksum based on look-up table as generated by CRC32POLY beforehand. The byte count can be any 32-bit value that is divisible by four, including zero. The DMA channel is disabled after completion, but the DMA status is not cleared so that in the event of an error the DMA can be debugged.

```
bool rom_MemCrc(void *pSrc, uint32_t ulCrcChk, uint32_t ulByteCnt);
```

|           |                                                                     |
|-----------|---------------------------------------------------------------------|
| PP Define | FUNC_ROM_MEMCRC                                                     |
| Prototype | bool rom_MemCrc(void *pSrc, uint32_t ulCrcChk, uint32_t ulByteCnt); |
| Arguments | R0: pSrc Source Address<br>R1: Reference Checksum<br>R2: Byte Count |

|                    |                             |
|--------------------|-----------------------------|
| Return Value       | 0: on success -1 on failure |
| Stack Requirements | none                        |

## Memory Fill

Mem Fill fills a specified region of memory with a 32-bit value provided. The byte count can be any 32-bit value that is divisible by four, including zero. The DMA channel is disabled after completion, but the DMA status is not cleared so that in the event of an error the DMA can be debugged.

```
bool rom_MemFill(void *pDst, uint32_t ulFillVal, uint32_t ulByteCnt);
```

|                     |                                                                       |
|---------------------|-----------------------------------------------------------------------|
| PP Define?          | FUNC_ROM_MEMFILL                                                      |
| Prototype?          | bool rom_MemFill(void *pDst, uint32_t ulFillVal, uint32_t ulByteCnt); |
| Arguments?          | R0: pDst DestinationAddress<br>R1: Fill Value<br>R2: Byte Count       |
| Return Value?       | 0: on success, -1 on failure                                          |
| Stack Requirements? | none                                                                  |

## Software Built-in Self Test

Provides entry to multiple Software-Based Functional Self-Testing routines.

```
ADI_SBST_RESULT rom_SBST(TEST_FUNC_ID, argument1, argument2, argument3);
```

|                     |                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PP Define?          | FUNC_ROM_SBST                                                                                                                                                              |
| Address             | 0xC8000084                                                                                                                                                                 |
| Prototype?          | ADI_SBST_RESULT rom_SBST(TEST_FUNC_ID, argument1, argument2, argument3);                                                                                                   |
| Arguments?          | R0: ID of function to be executed<br>R1: Argument 1 to be passed to function<br>R2: Argument 2 to be passed to function<br>[fp+ 0x14]: argument 3 to be passed to function |
| Return Value?       | struct ADI_SBST_RESULT<br>R0: ADI_SBST_RESULT.dResult<br>R1: ADI_SBST_RESULT.dErrorAddress                                                                                 |
| Stack Requirements? | valid stack (SP, FP dividable by 4) required.                                                                                                                              |

## **Booting Data Structures**

The programming model for booting the processor uses the data structures defined in this section.

## STRUCT\_ROM\_SYSCTRL

Syscontrol configuration parameter

```
struct STRUCT_ROM_SYSCTRL;
```

|          |                |                                         |
|----------|----------------|-----------------------------------------|
| uint32_t | ulCGU_CTL      | Content of Clock Control Register       |
| uint32_t | ulCGU_DIV      | Content of Clock Divide Register        |
| uint32_t | ulWUA_Flags    | Flags used during wakeup                |
| uint32_t | ulWUA_BootAddr | Memory boot address                     |
| uint32_t | ulWUA_User     | User variable                           |
| uint32_t | ulDMC_CTL      | Content of the DMC Control Register     |
| uint32_t | ulDMC_CFG      | Content of the DMC Config Register      |
| uint32_t | ulDMC_TR0      | Content of the DMC Timing Register 0    |
| uint32_t | ulDMC_TR1      | Content of the DMC Timing Register 1    |
| uint32_t | ulDMC_TR2      | Content of the DMC Timing Register 2    |
| uint32_t | ulDMC_MR       | Content of the DMC MR Shadow Register   |
| uint32_t | ulDMC_EMR1     | Content of the DMC EMR1 Shadow Register |
| uint32_t | ulDMC_EMR2     | Content of the DMC EMR2 Shadow Register |
| uint32_t | ulDMC_PADCTL   | Content of the DMC PADCTL register      |
| uint32_t | ulDMC_DLLCTL   | Content of the DMC DLLCTL register      |
| uint32_t | ulReserved     | Reserved entry                          |

## STRUCT\_ROM\_BOOT\_BUFFER

```
struct STRUCT_ROM_BOOT_BUFFER
```

|         |            |
|---------|------------|
| void    | *pBuffer   |
| int32_t | dByteCount |

## STRUCT\_ROM\_BOOT\_CONFIG

```
struct STRUCT_ROM_BOOT_CONFIG
```

|                        |                      |
|------------------------|----------------------|
| void                   | *pSource             |
| void                   | *pDestination        |
| uint32_t               | *pControlRegister    |
| uint32_t               | *pAuxControlRegister |
| uint32_t               | *pDmaControlRegister |
| uint32_t               | *pSecControlRegister |
| int32_t                | dControlValue        |
| int32_t                | dByteCount           |
| int32_t                | dFlags               |
| uint16_t               | uwDataWidth          |
| uint16_t               | uwSrcModifyMult      |
| uint16_t               | uwDstModifyMult      |
| uint16_t               | uwUserShort          |
| int32_t                | dUserLong            |
| int32_t                | dReserved            |
| void                   | *pModeData           |
| int32_t                | dBootCommand         |
| void                   | *pNextDxe            |
| ROM_BOOT_ERROR_FUNC    | *pErrorFunction      |
| ROM_BOOT_LOAD_FUNC     | *pLoadFunction       |
| ROM_BOOT_CALLBACK_FUNC | *pCallBackFunction   |

|                        |                   |
|------------------------|-------------------|
| ROM_BOOT_CALLBACK_FUNC | *pCrcFunction     |
| ROM_BOOT_CALLBACK_FUNC | *pForwardFunction |
| STRUCT_ROM_BOOT_HEADER | *pHeader          |
| void                   | *pTempBuffer      |
| int32_t                | dTempByteCount    |
| void                   | *pTempSource      |
| int32_t                | dPageByteCount    |
| uint32_t               | ulBlockCount      |
| uint32_t               | ulBlockCurrent    |
| int32_t                | dClock            |
| void                   | *pLogBuffer       |
| void                   | *pLogCurrent      |
| int32_t                | dLogByteCount     |

## STRUCT\_ROM\_BOOT\_HEADER

```
typedef struct STRUCT_ROM_BOOT_HEADER
```

|         |                 |
|---------|-----------------|
| int32_t | dBlockCode      |
| void    | *pTargetAddress |
| int32_t | dByteCount      |
| int32_t | dArgument       |

## STRUCT\_ROM\_BOOT\_SPI

```
struct STRUCT_ROM_BOOT_SPI
```

|          |                |
|----------|----------------|

| uint16_t | uwTxCtlUpper   |
| uint16_t | uwRxCtlUpper   |
| uint16_t | uReserved      |

## Wakeup From Hibernate

When the boot code detects that the chip is waking up from hibernate it can take some special actions. These include:

- Configuration of PLL (CGU\_DIV and CGU\_CTL registers)
- Initialization of DDR controller

- Memboot from any memory address

The special sequence executes when the RCU\_HBTRES hibernate reset identification bit is set. In case of a warm boot the RCU\_HBTRES bit can be overruled by the BCODE\_HBTOVW bit. When either of these bits is detected as a one, the boot code inspects the DPM\_RESTORE0 register for further instructions. At least two bits must be set in DPM\_RESTORE0 for the special action to take place.

Note the importance of this feature in case of slave boot modes. The Blackfin enters hibernate on its own decision. There is no direct path for this action to be directly controlled by the host (it might indirect thought). Therefore, do not assume that the host was aware of the processor being in the hibernate state.

On wakeup, the host may not know that the processor is expecting boot data. To prevent the processor from starving at wakeup, this special functionality enables the processor to boot from a LDR stream stored in off-chip memory (DDR or SMC SRAM). The stream may consist of one single 16-byte boot block header, which efficiently terminates the boot process and enables Core 0 to execute the code directly without further involvement of the boot code. Since even this one boot header is protected by XOR checksum the processor is prevented from booting illegal opcodes when the memory content was not in integer form.

When the WUA\_MEMBOOT and WUA\_ENA bits are set, after optional PLL and DDR initialization, the boot code does not continue with boot mode processing as per the BMODE pin configuration. Instead, the boot code performs a memory boot from the address specified by the WUA\_BOOT\_ADDR field. In case the address points to SMC space the memory boot mode automatically enables the respective SMC bank and required pin muxing.

## **CGU Initialization after Wakeup**

When the processor enters the hibernate state, the CGU current configuration is lost and at a wakeup event the default reset values become applicable. In order to provide more optimal processor configuration at wakeup, programs may save the required CGU configuration to the DPM0\_RESTORE registers. Upon detecting a wakeup event the boot code can optionally re-configure the CGU based on the contents of the DPM0\_RESTORE registers.

The WUA\_CLOCK bit of the DPM0\_RESTORE0 register defines whether the boot code should reconfigure the CGU or not. If the CGU is to be reconfigured then the CGU0\_DIV and the CGU0\_CTL registers are programmed based upon the contents of two of the DPM0\_RESTORE registers. See the registers section below for details of which registers are used during the configuration.

## **DDR Controller Initialization after Wakeup**

Before entering the hibernate state, the external SDRAM is placed in self-refresh mode in order to preserve the contents of memory. During hibernate the power to the DDR is cut-off, to lower power consumption. When the device exits the hibernate state the DDR is required to be re-initialized. In order for the DDR to be re-initialized, programs are required to save the current DDR configuration to the DPM\_RESTORE registers prior to the processor entering the hibernate state. The Syscontrol routine provides a means for

programs to restore the context prior to entering hibernate in a manner that is compatible with the required context restoration.

## BFLAG\_WAKEUP and BFLAG\_QUICKBOOT

Whenever either the RCU\_BCODE\_HBTOVW flag or the RCU\_STAT\_HBRST status bit is set, the main routine passes the BFLAG\_WAKEUP flag when calling the Boot routine. When called that way the underlying boot kernel watches for block headers for the BFLAG\_QUICKBOOT flag set. In the event of both flags being set, the boot kernel takes special action in the scope of the current block by:

- Toggling the BFLAG\_IGNORE flag
- Clearing the BFLAG\_INIT, BFLAG\_CALLBACK, BFLAG\_FORWARD, BFLAG\_AUX and BFLAG\_FINAL flags (as with any ignore block)
- Prevents fill blocks from processing (as with any ignore block)

Blocks that have BFLAG\_IGNORE=0 and BFLAG\_QUICKBOOT=1 are normally processed for a regular (non-wakeup) boot and are not processed for a wakeup boot. This way unnecessary rebooting of non-volatile memory cells can be avoided (speak external SRAM or SDRAM in self-refresh mode).

Blocks that have BFLAG\_IGNORE=1 and BFLAG\_QUICKBOOT=1 are ignored during regular boot and become active in case of wakeup. This supports complete arbitrate boot processing. Note that for FIRST blocks the IGNORE flag only controls the data load. The handling of the start vector and the next dx pointer is not conditional. To make the initcode processing conditional, keep the BFLAG\_QUICKBOOT flag clear for the init block and interrogate the BFLAG\_WAKEUP flag in the initcode itself.

The BFLAG\_SAVE flag is the BFLAG\_QUICKBOOT's counterpart and enables programs to implement special context savings strategies before entering hibernate. However, the boot code does not directly support this functionality.

The wakeup/quickboot mechanism can be re-purposed by controlling the BFLAG\_WAKEUP bit in the rom\_Boot() routine's dFlags argument, or by altering the flag from within hook or initcode routines.

## DPM Register List

The dynamic power management (DPM) unit includes the phase locked loop (PLL) enable/disable features, deep sleep and hibernate mode controls, and clock domain enable/disable features. The combination of these features and controls provide selective and flexible power management. A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

**Table 34-24:** DPM Module Registers

| Name               | Description                              |
|--------------------|------------------------------------------|
| DPM_CTL            | Control Register                         |
| DPM_STAT           | Status Register                          |
| DPM_CCBF_DIS       | Core Clock Buffer Disable Register       |
| DPM_CCBF_EN        | Core Clock Buffer Enable Register        |
| DPM_CCBF_STAT      | Core Clock Buffer Status Register        |
| DPM_CCBF_STAT_STKY | Core Clock Buffer Status Sticky Register |
| DPM_SCBF_DIS       | System Clock Buffer Disable Register     |
| DPM_WAKE_EN        | Wakeup Enable Register                   |
| DPM_WAKE_POL       | Wakeup Polarity Register                 |
| DPM_WAKE_STAT      | Wakeup Status Register                   |
| DPM_HIB_DIS        | Hibernate Disable Register               |
| DPM_PGCNTR         | Power Good Counter Register              |
| DPM_RESTOREn       | Restore n Register                       |

## DPM Restore

### DPM\_RESTORE0: DPM Restore Register 0 (R/W, 3V domain) - RW

Reset = 0x0000 0000

#### WUA\_DDR\_LOCK

Action on Wakeup from Hibernate

0 = Waits for (DSEL/CSEL)+1\*3000 CCLK cycles for DLL lock to occur

1 = Waits for (DSEL/CSEL)+1\*6000 CCLK cycles for DLL lock to occur

#### WUA\_DDR\_DLLEN

Action on Wakeup from Hibernate

0 = Do not restore DDR\_DLLCTL and DDR\_PADCTL registers

1 = Restore DDR\_DLLCTL and DRR\_PADCTL registers

#### WUA\_DDR

Action on Wakeup from Hibernate

0 = Do not initialize DDR controller

1 = Initialize DDR controller

#### WUA\_CLOCK

Action on Wakeup from Hibernate

0 = Do not initialize from CGU

1 = Initialize CGU

#### WUA\_ENA

Wakeup Sequencing Enable bit

0 = No special action is taken

1 = Special action is taken based on further instruction bits in this register

#### WUA\_CLOCK

Action on Wakeup from Hibernate

0 = Boot from regular BMODE source

1 = Boot from user address in memory

**Figure 34-26:** DPM Restore Register0

The following table describes the function of each of the restore registers. RESTORE0 and RESTORE1 are only registers that do not directly restore other registers. RESTORE0 serves as the control register, enabling the function of the rest, and RESTORE1 stores a boot address rather than data to restore a particular register.

**Table 34-25:** DPM Restore Values

| DPM Register | Restored Register   | Enable Bit  |
|--------------|---------------------|-------------|
| RESTORE1     | Address booted from | WUA_MEMBOOT |
| RESTORE2     | CGU_DIV             | WUA_CLOCK   |
| RESTORE3     | CGU_CTL             | WUA_CLOCK   |
| RESTORE4     | Reserved            | Reserved    |
| RESTORE5     | DDR_CTL             | WUA_DDR     |

**Table 34-25:** DPM Restore Values (Continued)

| DPM Register | Restored Register | Enable Bit             |
|--------------|-------------------|------------------------|
| RESTORE6     | DDR_CFG           | WUA_DDR                |
| RESTORE7     | DDR_TR0           | WUA_DDR                |
| RESTORE8     | DDR_TR1           | WUA_DDR                |
| RESTORE9     | DDR_TR2           | WUA_DDR                |
| RESTORE10    | DDR_MR            | WUA_DDR                |
| RESTORE11    | DDR_EMR1          | WUA_DDR                |
| RESTORE12    | DDR_EMR2          | WUA_DDR                |
| RESTORE13    | DDR_PADCTL        | WUA_DDR& WUA_DDR_DLLEN |
| RESTORE14    | DDR_DLLCTL        | WUA_DDR& WUA_DDR_DLLEN |
| RESTORE15    | Reserved          | Reserved               |

## Reset and Power-up

The processor implements several different power-up and reset scenarios ranging from a full power-on to software triggered resets. The Boot Kernel plays a specific role depending on the scenario.

### Reset Vector

When reset releases, the processor starts fetching and executing instructions at the on-chip boot ROM.

On a hardware reset the boot kernel initializes the `RCU_SVECT` register to `0xFFA00000`. When the booting process completes, the boot kernel jumps the location provided by the `RCU_SVECT` vector register. With the exception of the host DMA boot modes, the content of the `RCU_SVECT` register is overwritten by the target address field of the first block of the loaded boot stream. If the `BCODE` field of the `RCU_STAT` register is set to No-boot, the `RCU_SVECT` register is not modified by the boot kernel on software resets. Therefore, programs can control the reset vector for software resets through the `RCU_SVECT` register. The content of the register may be `RCU_SVECT` undefined in emulator sessions.

## Servicing Reset Interrupts

The reset interrupt has top priority and the processor services a reset event like other interrupts. Only emulation events have higher priority. When it comes out of reset, the processor is in supervisor mode and has full access to all system resources. The boot kernel can be seen as part of the reset service routine as it runs at top interrupt priority level.

Even when the boot process has finished and the boot kernel passes control to the user application, the processor is still in the reset interrupt. To enter the user mode, the reset service routine must initialize the RETI register and terminate by an RTI instruction.

Systems that do not work in an OS environment may not enter user mode. Typically, the interrupt level needs to be degraded down to IVG15.

**NOTE:** As the boot kernel is running at the reset interrupt priority,  $\overline{\text{NMI}}$  events, hardware errors, and exceptions are not served at boot time. As soon as the reset service routine returns, the processor may service the events that occurred during the boot sequence. It is recommended that programs install  $\overline{\text{NMI}}$ , hardware error and exception handlers before leaving the reset service routine. This includes proper initialization of the respective event vector registers, RCU\_SVECT

## NMI and RESOUT

The  $\overline{\text{NMI}}$  and  $\overline{\text{RESOUT}}$  signals share the same pin. When the part is in reset, the pin is in  $\overline{\text{RESOUT}}$  mode, and  $\overline{\text{RESOUT}}$  is asserted. The  $\overline{\text{NMI}}$  signal is disabled for the duration of this reset event. After the  $\overline{\text{RESOUT}}$  goes low the pin is automatically placed into  $\overline{\text{NMI}}$  mode and the  $\overline{\text{NMI}}$  signal is enabled.

This pin should be connected to an external pull-up.

## Memory Initialization

The first stage of booting initializes and validates all memory. This is performed before the actual boot process begins.

Memory Initialization occurs early in the boot process, before any stream information is read, and before the boot code has any influence. The boot kernel initializes all memory and cache tags and ensures all parity and ECC checksum bits are consistent with data. All memory is initialized to 0x00A700A7 or except 7;

Both cores are initialized. This infers that both cores will be woken up during this initial boot process. When booting from Core 0, upon completion of memory initialization, core 1 is left in the idle state. Core 1 can be used during the boot process using the API function.

## Debugging

This section describes how to bypass booting and execute code directly from SDRAM

If the boot process fails, very little information can be gained by watching the chip from outside. In master boot modes, the interface signals can be observed. In slave boot modes, only the `RESOUT` and `RTS` signals tell about the progress of the boot process.

The `RESOUT` signal is cleared after memory initializations are completed. The `RESOUT` and `NMI` signals share the same pin. During the boot process the `NMI` signal is disabled, once the `RESOUT` signal is asserted high upon completion of the boot process, the `NMI` signal is enable. Note that the `RESOUT` and `NMI` signals are active low and therefore require a pull-up resistor to be connected.

Using the emulator, however, there are many possibilities to debug the boot process. The entire source code of the boot kernel is provided with the tools installation. This includes the DSP executable (DXE) file. The *load symbols* feature of the tools environment helps to navigate the program. Note that the content of the ROM might differ between silicon revisions. Hardware breakpoints and single-stepping capabilities are also available. Since the content of the L1 instruction ROM cannot be read out by the emulator, as this ROM is not supported by the ITEST feature, these instructions are not displayed in the disassembly window. Table [Boot Kernel Symbol for Debug](#) shows several program symbols that may be of interest.

**Table 34-26:** Boot Kernel Symbol for Debug

| Symbol                                      | Comment                                                                                                                                                                                                                                        |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_bootrom.bootmenu</code>              | If the emulator hits a hardware breakpoint at the <code>_bootrom.bootmenu</code> address, this indicates that the preboot returned properly. Otherwise the program may hang during preboot due to improper PBS settings or invalid boot modes. |
| <code>_bootrom.bootkernel.entry</code>      | If the emulator hits a hardware breakpoint at the <code>_bootrom.bootkernel.entry</code> label, this indicates that device detection or autobaud returned properly.                                                                            |
| <code>_bootrom.bootkernel.breakpoint</code> | This is a good address to place a hardware breakpoint. When hit the boot kernel has a new block header loaded in. The block header can be watched at address wherever the <code>pHeader</code> points to.                                      |
| <code>_bootrom.bootkernel.initcode</code>   | All payload data of the current block has been loaded by the time the program passes this label. The boot kernel is about to interrogate the <code>BFLAG_INITCODE</code> flag. If set, the <code>initcode</code> can be debugged.              |
| <code>_bootrom.bootkernel.exit</code>       | Once the boot kernel arrives at this label, it has detected a <code>BFLAG_FINAL</code> flag. After some housekeeping, it jumps to the <code>EVT1</code> vector.                                                                                |

The boot kernel also generates a circular log file in scratch pad memory. While the `pLogBuffer` and the `dLogByteCount` variables describe the location and dimension of the log buffer, the `pLogCurrent` points to the next free location in the buffer. The log file is updated whenever the kernel passes the `_bootrom.bootkernel.breakpoint` label.

At each pass, nine 32-bit words are written to the log file, as follows.

- the block code word (dBlockCode) of the block header
- the target address (dTargetAddress) of the block header
- the byte count (dByteCount) of the block header
- the argument word (dArgument) of the block header
- the source pointer (dSource) of the boot stream
- the block count (dBlockCount)
- an internal copy of the dBlockCode word OR'ed with dFlags
- the content of the SEQSTAT register
- a 0xFFFFFFFFFA constant

The ninth word is overwritten by the next entry set, so that 0xFFFFFFFFFA always marks the last entry in the log file. Most of the data structures used by the boot kernel reside of the stack in scratch pad memory. While executing the boot kernel routine (excluding subroutines) the P5 point to the *STRUCT\_ROM\_BOOT\_CONFIG* structure. Type *STRUCT\_ROM\_BOOT\_CONFIG\**) \$P5 in the IDDE expression window to see the structure content.

The *Error Handler* can also give indications of errors. See the API documentation for more information.

## Boot ROM Revision Control

Describes the provisions for reading ROM version on the processor

### Boot ROM Revision Control

The boot ROM reserves the 32-bit location at address 0xC8000040 for a version code consisting of four bytes as shown in the *ROM Revision Control*.

Revision: Memory location with ROM revision information -

Figure 34-27: ROM Revision Control

# Booting Register Reference

This section provides reference information regarding the registers used during the booting process.

## Status Register

The RCU status register (RCU\_STAT) contains status bits for all RCU reset sources, reset status, and boot mode inputs. Status bits for reset sources are sticky and can be cleared by software. Error status bits are cleared by any reset event.

**RCU\_STAT: Status Register - R/W**

Reset = 0x0000 0021

**Figure 34-28:** RCU\_STAT Register Diagram

**Table 34-27:** RCU\_STAT Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                           |
|---------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18      | RSTOUTERR | Reset Out Error.<br>The RCU_STAT . RSTOUTERR bit indicates (if set) that a write attempted to set the RCU_CTL . RSTOUTASRT and RCU_CTL . RSTOUTDSRT simultaneously. This condition triggers a bus error.                                                          |
|         |           | 0 No Error                                                                                                                                                                                                                                                        |
|         |           | 1 Error Occurred                                                                                                                                                                                                                                                  |
| 17      | LWERR     | Lock Write Error.<br>The RCU_STAT . LWERR bit indicates (when set) there was an attempted write to an RCU register while the the RCU_CTL . LOCK bit was set and the global lock bit is enabled (SPU_CTL_GLCK bit =1). This status bit is sticky; write-1-to-clear |
|         |           | 0 No Error                                                                                                                                                                                                                                                        |
|         |           | 1 Error Occurred                                                                                                                                                                                                                                                  |

**Table 34-27:** RCU\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | ADDRERR  | Address Error.<br>The RCU_STAT.ADDRERR bit indicates that the RCU generated an address error. This status bit is sticky; write-1-to-clear it.                                                                                                                                        |
|         |          | 0 No Error                                                                                                                                                                                                                                                                           |
|         |          | 1 Error Occurred                                                                                                                                                                                                                                                                     |
| 11:8    | BMODE    | Boot Mode.<br>The RCU_STAT.BMODE bits indicate the input on the boot mode pins.                                                                                                                                                                                                      |
| 5       | RSTOUT   | Reset Out Status.<br>The RCU_STAT.RSTOUT bit indicates the assertion status of the system reset pin.                                                                                                                                                                                 |
|         |          | 0 RSTOUT Deasserted                                                                                                                                                                                                                                                                  |
|         |          | 1 RSTOUT Asserted                                                                                                                                                                                                                                                                    |
| 3       | SWRST    | Software Reset.<br>The RCU_STAT.SWRST bit indicates that a system reset (which was triggered by software) has occurred since the last time a hardware reset occurred or since the RCU_STAT.SWRST bit was cleared by software.                                                        |
|         |          | 0 Inactive                                                                                                                                                                                                                                                                           |
|         |          | 1 Reset Occurred                                                                                                                                                                                                                                                                     |
| 2       | SSRST    | System Source Reset.<br>The RCU_STAT.SSRST bit indicates that a system reset triggered by hardware in the system clock domain, clock A domain, or clock B domain has occurred since the last time a hardware reset occurred or since the RCU_STAT.SSRST bit was cleared by software. |
|         |          | 0 Inactive                                                                                                                                                                                                                                                                           |
|         |          | 1 Reset Occurred                                                                                                                                                                                                                                                                     |

**Table 34-27:** RCU\_STAT Register Fields (Continued)

# 35 System Debug Unit (SDU)

The System Debug Unit (SDU) provides debug access to the connected system. It provides debug host interface support through a JTAG (IEEE-1149.1) interface. In addition to traditional JTAG features, the SDU provides direct access to system resources to enable highly flexible and non intrusive debug support. The SDU can control and communicate with cores through JTAG or (if supported by the core) through system transactions. The SDU can perform system transactions as a system master through the memory access controller interface (MAC) and its memory mapped registers can be accessed by system masters through the slave port.

## SDU Features

- System JTAG TAP controller for system debug features, boundary scan, and public JTAG features
- Provides debug interface to core(s), and other system resources
- Provides direct and runtime access to memory system and system MMRs
- Provides DMA and non-DMA access to memory spaces
- SDU registers accessible to debug host and system (system MMRs)
- Support for system watchpoint and other event signaling
- Direct control over system reset
- Provides support for debug immediately after reset (boot debug)
- Supports group halt (debug event immediately halts all specified endpoints)

## SDU Functional Description

The following sections provide a functional description of the SDU.

- [\*SDU Register List\*](#)
- [\*ADSP-BF60x SDU Interrupt List\*](#)
- [\*SDU Block Diagram\*](#)
- [\*JTAG Tap Controller \(JTC\) Block Diagram\*](#)
- [\*Memory Access Controller \(MAC\)\*](#)

- [Group Halt](#)

## SDU Register List

The system debug unit (SDU) provides IEEE-1149.1 support through its JTAG interface. The registers listed in the SDU register summary table govern SDU operations. For more information on SDU functionality, see the SDU register descriptions.

**Table 35-1:** SDU Module Registers

| Name        | Description                    |
|-------------|--------------------------------|
| SDU_IDCODE  | ID Code Register               |
| SDU_CTL     | Control Register               |
| SDU_STAT    | Status Register                |
| SDU_MACCTL  | Memory Access Control Register |
| SDU_MACADDR | Memory Access Address Register |
| SDU_MACDATA | Memory Access Data Register    |
| SDU_DMARD   | DMA Read Data Register         |
| SDU_DMAWD   | DMA Write Data Register        |
| SDU_MSG     | Message Register               |
| SDU_MSG_SET | Message Set Register           |
| SDU_MSG_CLR | Message Clear Register         |
| SDU_GHLT    | Group Halt Register            |

## ADSP-BF60x SDU Interrupt List

**Table 35-2:** ADSP-BF60x SDU Interrupt List

| Description | ID | DMA Channel | Sensitivity |
|-------------|----|-------------|-------------|
| SDU0 DMA    | 64 | 11          | LEVEL       |

## ADSP-BF60x SDU Trigger List

**Table 35-3:** Masters ADSP-BF60x SDU Trigger List

| Description | ID | Sensitivity |
|-------------|----|-------------|
| SDU0 DMA    | 31 | PULSE/EDGE  |
|             |    |             |

**Table 35-4:** Slaves ADSP-BF60x SDU Trigger List

| Description        | ID | Sensitivity |
|--------------------|----|-------------|
| SDU0 DMA           | 31 |             |
| SDU0 Slave Trigger | 69 |             |
|                    |    |             |

## SDU Definitions

To make the best use of the SEC, it is useful to understand the following terms.

### *JTAG 1149.1*

IEEE Standard Test Access Port and Boundary-Scan Architecture.

### **Group Halt**

Synchronous halt of distributed bus masters and various peripherals.

### **MAC**

Memory Access Controller, system master interface controlled by the SDU

### **System Bus**

In the context of the SDU definition this refers to the system interconnect fabric of the given product.

## SDU Block Diagram

The SDU architectural model is illustrated in the following figure. The figure is a block diagram of the SDU and the associated debug connections of the system.

## JTAG Tap Controller (JTC) Block Diagram

The SDU includes a JTAG tap controller to support the IEEE-1149.1 standard. The JTAG tap controller implements the traditional state machine for the TAP controller and the necessary support for the implemented scan chains. The figure below shows the JTAG (IEEE1149.1) TAP controller state machine.

**Figure 35-1:** JTAG TAP Controller

## JTC Core Emulation

Each core has its own JTAG tap controller in addition to the JTC. The core JTAG tap controllers are bypassed (not in the scan path) after reset. They can be added to the scan path under control of the SDU\_CTL register. Each core JTAG controller provides support for the core only feature set (step, core register access and others). The following figure illustrates the connection model.

JTC Instruction Register (IR)

The Instruction Register of the JTC is five bits wide. Decode of the Instruction Register selects which of the SDU scan registers is to be connected between TDI and TDO pins during scan operation. The SDU scan registers provide support for JTAG Public Instructions and private (SDU) registers for debug control and status.

The following tables list the JTAG scan registers with their corresponding instruction decode. Instruction decode values not listed are reserved and must not be accessed.

Table 35-5: JTAG Public Scan Registers

| Instruction Decode (TDI->TDO) | Instruction Names | Register Name                              | Width            |
|-------------------------------|-------------------|--------------------------------------------|------------------|
| 00000                         | Extest            | Boundary Scan                              | Product Specific |
| 10000                         | Sample/Preload    | Boundary Scan                              | Product Specific |
| 00010                         | IDCODE            | CHIPID - Constant (Product Specific) value | 32               |
| 11111                         | Bypass            | Bypass                                     | 1                |

Table 35-6: SDU Scan Registers

| Instruction Decode (TDI->TDO) | Instruction Names | Register Name        | Width |
|-------------------------------|-------------------|----------------------|-------|
| 00101                         | SDU_CTL           | SDU Control Register | 16    |

**Table 35-6:** SDU Scan Registers (Continued)

| Instruction Decode<br>(TDI->TDO) | Instruction Names | Register Name                                          | Width |
|----------------------------------|-------------------|--------------------------------------------------------|-------|
| 10101                            | SDU_STAT          | SDU Status Register                                    | 32    |

| 10111                            | SDU_SCANMODE      | Scan Mode Enable Register for DFT Scan Chains          | 1     |
| 11011                            | SDU_SCANATSPEED   | Scan At Speed Mode Enable Register for DFT Scan Chains | 1     |

## Memory Access Controller (MAC)

The MAC implements control functions to provide support for access to system memory space (for example L1, L2, L3, System MMRs). These functions support debug host features like Background Telemetry Channel (BTC), Code and Data download. The MAC supports two types of functions

1. MAC Direct access
2. MAC DMA access

### MAC Direct Access

The MAC provides direct access to system memory and system MMRs. This function provides access to individual addresses through address (MACADDR), data (MACDATA), and control (MACCTL) registers. When

the debug host needs to perform a memory access it loads these three registers with address, data, and control values. The act of writing to the control register triggers the MAC state machine to initiate a transfer request on the MAC system interface.

The `MACRDY` bit in the `SDU_STAT` register indicates when the MAC is ready for a new transfer. In the case of the previous operation being a read transfer, `MACRDY` also indicates that read data has been returned in the `MACDATA` register.

## **MAC DMA Access**

The MAC provides DMA access to system memory to improve the efficiency of debug host communication. The MAC DMA interface provides the following:

- DMA FIFO
- DMA data registers
  - DMA Write Data register (`SDU_DMAWD`)
  - DMA Read Data register (`SDU_DMARD`)

The DMA FIFO is 4-bytes wide and connected to a system DMA channel on one side and to the `SDU_DMARD` and `SDU_DMAWD` registers on the other.

The DMA Interface registers act as the interface points to the DMA FIFO. Depending upon the direction of a DMA transfer, the `SDU_DMAWD` is used to fill the DMA FIFO, or the `SDU_DMARD` is used to empty the DMA FIFO.

## **Group Halt**

The SDU provides support for a user defined group halt model. The model allows for the masters and slaves of the group halt assertion to be selectable. Each master provides support for event signaling to the SDU for group halt assertion. Each slave provides support for responding to a group halt assertion.

The programming model consists primarily of a system MMR in the SDU (`SDU_GHLT`) to configure the masters and slaves of group halt. An overview of the signaling involved for group halt is shown in the following figure (example signal names shown for illustration purpose only):

## Group Halt Status

Group Halt status and Group Halt Cause (master) are captured in the `SDU_STAT` register. The cause is captured upon assertion of the status. First cause is the only one captured. This information will be used to indicate to the debug host that group halt was asserted and which master generated the group halt. The System Halt signal (from the Group Halt Overview figure) is the indication for non-core system masters to halt if configured to do so. `SDU_STAT.GHLT` is the source of the System Halt if System is selected as a slave. For the system to resume (deassertion of System Halt), `SDU_STAT.GHLT` must be cleared by a W1C operation.

## Group Halt Masters

If “core n” generates a debug event (for example software breakpoint) it asserts its debug mode indication signal (for example `EMUSPACE`) to the SDU. If “core n” is enabled as a master of group halt, the SDU sets `GHLT` and capture `GHLTC` in `SDU_STAT`.

If the system generates a debug event (for example SDU trigger input, system watchpoint event) it asserts the corresponding signal to the SDU. If the system is enabled as a master of group halt, the SDU sets `GHLT` and captures `GHLTC` in the `SDU_STAT` register.

System debug events may be disabled at the source as necessary (for example System Watchpoint event indication to SDU may be disabled in the System Watchpoint Unit).

## Group Halt Slaves

When Group Halt status (`SDU_STAT.GHLT`) is asserted, the SDU asserts the debug request signal (for example `EMUINT`) to selected cores according to the settings in the `SDU_GHLT` register. The debug request to a core is asserted based on the transition of `GHLT` from 0 to 1).

When Group Halt status (`SDU_STAT.GHLT`) is asserted, the SDU asserts the System Halt signal if System is selected as a slave in the `SDU_GHLT` register.

Each system master has a dedicated control bit to specify its response to a System Halt signal assertion. Typically this response is to halt the system which may have the following local implications:

1. Stop issuing system transactions
2. Pause the entire block
3. Both

## **SDU Programming Concepts**

### **Core Control**

Cores are directly controlled through emulation space. Core emulation space is entered by generating the core emulation interrupt. To do this, emulation and the emulation interrupt must be enabled in the appropriate core control register.

The SDU generates an emulator interrupt with the rising edge of the TMS pin when the JTAG TAP controller in SDU is in the Run-Test-Idle state. The processor core(s) enters emulation space in response to the emulation interrupt from SDU. The SDU generates an emulation interrupt to a core if the specific core is selected in the SDU control register (`EHLT` field). Once in emulation space, the core executes operations as directed by the debug host. Processor instructions are scanned in and executed using the core emulation instruction register (for example `EMUIR`) and the core emulation data register (for example `EMUDAT`). The JTAG TAP controller is used to perform the scan operations.

### **Memory and Register Access**

Memory and register access is performed using one of the following two methods.

- Direct: Memory and registers that are mapped into the system address space may be accessed directly by the SDU system interfaces (for example `MAC`).
- Indirect: Memory and registers that are not mapped into the system address space may only be accessed indirectly through core instruction execution while in emulation space (see Core Control).

### **Background Telemetry Channel (BTC)**

The BTC provides communication between the system and the debug host. System memory is required for BTC operation and must be allocated by the application for BTC use. The processor application

sends/receives messages to/from the debug host through the dedicated system memory space. The debug host accesses the BTC system memory space through the SDU MAC (the DMA channel).

## Statistical Profiling

Cores may support runtime statistical profiling by providing a register that samples the core PC in a pseudo-random fashion. The debug host accesses the core register (for example `EMUPC`) through JTAG scan operations.

## Power Management Support

A processor may support various power saving modes which may impair the ability for a debug host to communicate with the processor resources because the debug host may not be able to detect when the processor enters or exits such modes. The SDU provides the following support for the debug host to determine the power mode.

- **Core Clock(s) Stopped:** Power management may support a mode (for example Sleep) which stops the core clock(s). In this mode the SDU is unable to communicate with some system resources (for example core registers, core memory). The power management resource (for example Dynamic Power Management or DPM) typically remains accessible. The debug host, through the SDU MAC, may access the status register(s) in DPM to determine the state of the processor.
- **System Clock(s) Stopped:** Power Management may support a mode (for example Deep Sleep) which stops the system clock(s). In this mode the SDU is unable to communicate with all system resources including the power management resource (for example Dynamic Power Management). The SDU provides an input and associated status bit for the DPM to provide an indication of this power mode. The debug host may scan the SDU status register (`SDU_STAT`) through JTAG.

## System Reset Support

The SDU may indirectly generate a system reset. When set, the system reset bit (`SYSRST`) in the CTL register signals a system reset request to the Reset Control Unit (RCU). In response, the RCU asserts the system reset signal. Other events in the system can also cause the RCU to issue a system reset. In response to the system reset signal from RCU, all registers in the SDU are reset, except for the CTL register. The SDU provides an indication that system reset has occurred (`SDU_STAT.SYSRST`). See registers description section for more detail.

## SDU Register Descriptions

System Debug Unit (SDU) contains the following registers.

**Table 35-7:** SDU Module Registers

| Name        | Description                    |
|-------------|--------------------------------|
| SDU_IDCODE  | ID Code Register               |
| SDU_CTL     | Control Register               |
| SDU_STAT    | Status Register                |
| SDU_MACCTL  | Memory Access Control Register |
| SDU_MACADDR | Memory Access Address Register |
| SDU_MACDATA | Memory Access Data Register    |
| SDU_DMARD   | DMA Read Data Register         |
| SDU_DMAWD   | DMA Write Data Register        |
| SDU_MSG     | Message Register               |
| SDU_MSG_SET | Message Set Register           |
| SDU_MSG_CLR | Message Clear Register         |
| SDU_GHLT    | Group Halt Register            |

## ID Code Register

The SDU ID code register (SDU\_IDCODE) contains bit fields describing the processor silicon revision, product identification, and manufacturer identification.

SDU\_IDCODE: ID Code Register - R/NW

Reset = 0x0000 00cb

Figure 35-2: SDU\_IDCODE Register Diagram

Table 35-8: SDU\_IDCODE Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:28   | REVID    | Revision ID.            |
| 27:12   | PRID     | Product ID.             |
| 11:1    | MFID     | Manufacturer ID.        |
| 0       | NA       | Reserved.               |

Control Register

The SDU control register (SDU\_CTL) contains bit fields enabling or disabling emulator features. This register may be reset only by asserting the SDU\_TRST pin.

SDU\_CTL: Control Register - R/NW

Reset = 0x0000 0000

**Figure 35-3:** SDU\_CTL Register Diagram

**Table 35-9:** SDU\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | EHLT     | Emulator Halt Select.<br>The SDU_CTL . EHLT selects system components to halt on assertion of the SDU_STAT . EME bit.                                                                                                                                                                         |

## Status Register

The SDU status register (`SDU_STAT`) contains bit fields describing debug-related processor status.

## SDU\_STAT: Status Register - R/W

Reset = 0x0000 0101

**Table 35-10:** SDU\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                           |          |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 22      | CRST     | Core Reset.<br>The <code>SDU_STAT.CRST</code> indicates the core reset has been asserted to one or more of the cores in the system. The core debug status register indicates which core or cores have been reset. |          |
|         |          | 0                                                                                                                                                                                                                 | Inactive |
|         |          | 1                                                                                                                                                                                                                 | Active   |
| 21      | CHLT     | Core Halt.<br>The <code>SDU_STAT.CHLT</code> indicates one or more of the cores in the system are halted. The core debug status register indicates which core or cores have halted.                               |          |
|         |          | 0                                                                                                                                                                                                                 | Inactive |
|         |          | 1                                                                                                                                                                                                                 | Active   |

**Table 35-10:** SDU\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |          |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| 20      | EME      | Emulation Event.<br>The <code>SDU_STAT.EME</code> indicates an emulation event is active and is set when the <code>SDU_TMS</code> pin transitions from 0-to-1 while the <code>SDU_CTL.EMEEN</code> bit is set. The <code>SDU_STAT.EME</code> bit transition to 1 serves as the source for core halt assertion as part of <code>SDU_CTL.EMEEN</code> selection. The emulator clears <code>SDU_STAT.EME</code> with a W1C operation, clearing <code>SDU_STAT.EME</code> for the next core halt by emulation. <code>SDU_STAT.EME</code> is the source for system halt assertion as part of <code>SDU_CTL.EHLT</code> selection. So, event response software must clear <code>SDU_STAT.EME</code> to resume system operation. |          |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Inactive |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Active   |
| 19:17   | GHLTC    | Group Halt Cause.<br>The <code>SDU_STAT.GHLTC</code> identifies the group halt master. The SDU updates the <code>SDU_STAT.GHLTC</code> bits on <code>SDU_STAT.GHLT</code> assertion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |          |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | System   |

|         |          | 7                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Reserved |
| 16      | GHLT     | Group Halt.<br>The <code>SDU_STAT.GHLT</code> indicates that group halt has been asserted by one of the group halt masters. On <code>SDU_STAT.GHLT</code> assertion, the SDU updates <code>SDU_STAT.GHLTC</code> with the value identifying the group halt cause. <code>SDU_STAT.GHLT</code> is the source for system halt assertion as part of group halt slave selection with the <code>SDU_GHLT.SS0-SDU_GHLT.SS2</code> bits. So, halt response software must clear <code>SDU_STAT.GHLT</code> to resume system operation.                                                                                                                                                                                             |          |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Inactive |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Active   |

|         |          | 1 Active                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 10      | DMAWDRDY | DMAWD Ready.<br>The <code>SDU_STAT.DMAWDRDY</code> indicates whether the <code>SDU_DMAWD</code> register is ready for the next transfer. When new data is written to the <code>SDU_DMAWD</code> register, the <code>SDU_STAT.DMAWDRDY</code> bit is cleared. When the write data is pushed into the DMA FIFO from the <code>SDU_DMAWD</code> register, the <code>SDU_STAT.DMAWDRDY</code> bit is set, indicating that it is safe to bring in next piece of write data for the DMA transfer. If <code>SDU_DMAWD</code> is written while <code>SDU_STAT.DMAWDRDY</code> is not set, the <code>SDU_STAT</code> register's <code>SDU_STAT.ERR</code> bit in is set (indicating an overflow condition) and the <code>SDU_STAT.ERRC</code> field is updated (indicating the overflow). |

**Table 35-10:** SDU\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| 9       | DMARDRDY | DMARD Ready.<br>The <code>SDU_STAT.DMARDRDY</code> indicates whether the <code>SDU_DMARD</code> register is ready for the next transfer. When data is read from the <code>SDU_DMARD</code> register, the <code>SDU_STAT.DMARDRDY</code> bit is cleared. When the new read data is loaded into the <code>SDU_DMARD</code> register from the DMA FIFO, the <code>SDU_STAT.DMARDRDY</code> bit is set, indicating that it is safe read (scan out) the next piece of read data for the DMA transfer. If <code>SDU_DMARD</code> is read (scanned out) while <code>SDU_STAT.DMARDRDY</code> is not set, the <code>SDU_STAT</code> register's <code>SDU_STAT.ERR</code> bit in is set (indicating an underflow condition) and the <code>SDU_STAT.ERRC</code> field is updated (indicating the underflow). The <code>SDU_STAT.DMARDRDY</code> bit is cleared when the read data is placed on the scan chain during JTAG scan operation. |           |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Not Ready |

Table 35-10: SDU\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                               |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | ERR      | Error.<br>The SDU_STAT.ERR indicates an SDU related error. The SDU updates SDU_STAT.ERRC on assertion SDU_STAT.ERR with the value identifying the error cause. SDU_STAT.ERRC only captures the first error on SDU_STAT.ERR assertion. |
|         |          | 0 Inactive                                                                                                                                                                                                                            |
|         |          | 1 Active                                                                                                                                                                                                                              |
| 0       | SYSRST   | System Reset.<br>The SDU_STAT.SYSRST indicates that system reset has been asserted. The assertion of system reset sets SDU_STAT.SYSRST.                                                                                               |
|         |          | 0 Inactive                                                                                                                                                                                                                            |
|         |          | 1 Active                                                                                                                                                                                                                              |

Memory Access Control Register

The SDU memory access control register (SDU\_MACCTL) contains bit fields configuring memory access features.

SDU\_MACCTL: Memory Access Control Register - R/W

Reset = 0x0000 0002

Figure 35-5: SDU\_MACCTL Register Diagram

**Table 35-11:** SDU\_MACCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | AUTOINC  | Auto (Post) Increment MACADDR (by SIZE).<br>The <code>SDU_MACCTL.AUTOINC</code> enables auto (post) increment of the <code>SDU_MACADDR</code> register value by the <code>SDU_MACCTL.SIZE</code> selection. |
|         |          | 0      Inactive                                                                                                                                                                                             |
|         |          | 1      Active                                                                                                                                                                                               |
| 3       | RNW      | Read Not Write.<br>The <code>SDU_MACCTL.RNW</code> selects read or write operation for the MAC transfer.                                                                                                    |
|         |          | 0      Write                                                                                                                                                                                                |
|         |          | 1      Read                                                                                                                                                                                                 |
| 2:0     | SIZE     | Transfer Data Size.<br>The <code>SDU_MACCTL.SIZE</code> selects the size of the data in the <code>SDU_MACDATA</code> register for the MAC transfer.                                                         |
|         |          | 0      8b                                                                                                                                                                                                   |
|         |          | ...      Reserved                                                                                                                                                                                           |
|         |          | 1      16b                                                                                                                                                                                                  |
|         |          | 2      32b                                                                                                                                                                                                  |
|         |          | 3      Reserved                                                                                                                                                                                             |
|         |          | 7      Reserved                                                                                                                                                                                             |

## Memory Access Address Register

The SDU memory access address register (`SDU_MACADDR`) contains the address of the MAC transfer.

SDU\_MACADDR: Memory Access Address Register - R/W

Reset = 0x0000 0000

Figure 35-6: SDU\_MACADDR Register Diagram

Table 35-12: SDU\_MACADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                           |
|---------|----------|-----------------------------------------------------------------------------------|
| 31:0    | ADDR     | Transfer Address.<br>The SDU_MACADDR.ADDR holds the address for the MAC transfer. |

Memory Access Data Register

The SDU memory access data register (SDU\_MACDATA) contains the data for the MAC transfer.

SDU\_MACDATA: Memory Access Data Register - R/W

Reset = 0x0000 0000

Figure 35-7: SDU\_MACDATA Register Diagram

Table 35-13: SDU\_MACDATA Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                     |
|---------|----------|-----------------------------------------------------------------------------|
| 31:0    | DATA     | Transfer Data.<br>The SDU_MACDATA.DATA holds the data for the MAC transfer. |

## DMA Read Data Register

The SDU DMA read data register (SDU\_DMARD) contains the data for the DMA read transfer.

**SDU\_DMARD: DMA Read Data Register - R/W**

Reset = 0x0000 0000

**Figure 35-8:** SDU\_DMARD Register Diagram

**Table 35-14:** SDU\_DMARD Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                              |
|---------|----------|--------------------------------------------------------------------------------------|
| 31:0    | VALUE    | Read Transfer Data.<br>The SDU_DMARD.VALUE holds the data for the DMA read transfer. |

## DMA Write Data Register

The SDU DMA write data register (SDU\_DMAWD) contains the data for the DMA write transfer.

**SDU\_DMAWD: DMA Write Data Register - R/W**

Reset = 0x0000 0000

**Figure 35-9:** SDU\_DMAWD Register Diagram

Table 35-15: SDU\_DMAWD Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                |
|---------|----------|----------------------------------------------------------------------------------------|
| 31:0    | VALUE    | Write Transfer Data.<br>The SDU_DMAWD.VALUE holds the data for the DMA write transfer. |

Message Register

The SDU message register (SDU\_MSG) holds user defined messages to pass to or to get from the debugger.

SDU\_MSG: Message Register - R/W

Reset = 0x0000 0000

Figure 35-10: SDU\_MSG Register Diagram

**Table 35-16:** SDU\_MSG Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                       |
|---------|------------|---------------------------------------------------------------|
| 31      | CALLERR    | Flag Set by the Boot Code Prior to an Error Call.             |
| 30      | CALLBACK   | Flag Set by the Boot Code Prior to a Callback Call.           |
| 29      | CALLINIT   | Flag Set by the Boot Code Prior to an Initcode Call.          |
| 28      | CALLAPP    | Flag Set by the Boot Code Prior to an Application Call.       |
| 27      | HALTONERR  | Generate an Emulation Exception Prior to an Error Call.       |
| 26      | HALTONCALL | Generate an Emulation Exception Prior to a Callback Call.     |
| 25      | HALTONINIT | Generate an Emulation Exception Prior to an Initcode Call.    |
| 24      | HALTONAPP  | Generate an Emulation Exception Prior to an Application Call. |
| 23      | L3INIT     | Indicates that the L3 Resource is Initialized.                |
| 22      | L2INIT     | Indicates that the L2 Resource is Initialized.                |
| 17      | C1L1INIT   | Indicates that the Core 1 L1 Resource is Initialized.         |
| 16      | C0L1INIT   | Indicates that the Core 0 L1 Resource is Initialized.         |

## Message Set Register

The SDU message set register (SDU\_MSG\_SET) is a write-1-set alias for the SDU\_MSG register.

### SDU\_MSG\_SET: Message Set Register - R/W

Reset = 0x0000 0000

**Figure 35-11:** SDU\_MSG\_SET Register Diagram

**Table 35-17:** SDU\_MSG\_SET Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | Message Set Value.<br>The SDU_MSG_SET.VALUE acts as a write-1-set alias for the SDU_MSG register. Writing a 1 to any bit in SDU_MSG_SET sets the corresponding bit in SDU_MSG. |

Message Clear Register

The SDU message clear register (SDU\_MSG\_CLR) is a write-1-clear alias for the SDU\_MSG register.

SDU\_MSG\_CLR: Message Clear Register - R/W

Reset = 0x0000 0000

**Figure 35-12:** SDU\_MSG\_CLR Register Diagram

**Table 35-18:** SDU\_MSG\_CLR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | Message Clear Value.<br>The SDU_MSG_CLR.VALUE acts as a write-1-clear alias for the SDU_MSG register. Writing a 1 to any bit in SDU_MSG_CLR clears the corresponding bit in SDU_MSG. |

Group Halt Register

The SDU group halt register (SDU\_GHLT) configures the master and slave selections for group halt.

SDU\_GHLT: Group Halt Register - R/W

Reset = 0x0000 0000

Figure 35-13: SDU\_GHLT Register Diagram

Table 35-19: SDU\_GHLT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                     |              |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| 18      | SS2      | Slave Select 2.<br>The SDU_GHLT.SS2 selects core 1 slave for group halt. On SDU_STAT.GHLT assertion, a halt command is issued to the slave. |              |
|         |          | 0                                                                                                                                           | Not Selected |
|         |          | 1                                                                                                                                           | Selected     |
| 17      | SS1      | Slave Select 1.<br>The SDU_GHLT.SS1 selects core 0 slave for group halt. On SDU_STAT.GHLT assertion, a halt command is issued to the slave. |              |
|         |          | 0                                                                                                                                           | Not Selected |
|         |          | 1                                                                                                                                           | Selected     |
| 16      | SS0      | Slave Select 0.<br>The SDU_GHLT.SS0 selects system slave for group halt. On SDU_STAT.GHLT assertion, a halt command is issued to the slave. |              |
|         |          | 0                                                                                                                                           | Not Selected |

## 36 System Watchpoint Unit (SWU)

The system watchpoint unit (SWU) is a single module used for transaction monitoring. The SWU is attached to each system slave through the system crossbar interface and provides ports for all system crossbar address channel signals. The SWU does not have ports for the read/write data channel signals or the low-power interface signals.

Each SWU contains four match groups of registers with associated hardware. These four SWU match groups operate independently, but share common event (interrupt and trigger) outputs. Each match group can monitor either the write or read address channel and can operate in either watchpoint mode or bandwidth mode.

### SWU Features

- Four independent match groups for each SWU
- Each match group can operate in either bandwidth mode or watchpoint mode

### SWU Functional Description

This section describes the function of the SWU match block, interface block and MMR block.

#### Match Block

There are four match blocks for each SWU. Each SWU match block can monitor either the read or write address channel, selected by the `SWU_CTL.DIR` bit, and can operate in either watchpoint or bandwidth mode, selected by the `SWU_CTL.BWEN` bit.

In either mode, the SWU match block can be programmed to match based on address (exact, inclusive/exclusive range), ID (with masking), security, and lock type. All enabled matches are AND'ed together to determine a match.

### SWU Register List

The system watchpoint unit (SWU) provides debug and development support through flexible transaction level and bandwidth monitoring and associated event triggering. The SWU generates an events based on monitoring transactions at the system slaves using four watchpoint match groups. The transaction monitoring within each match group may be filtered by address, ID, direction, and other watchpoint attributes.

An event may be a trace message, trigger, or interrupt. The desired event behavior is programmed into the appropriate system watchpoint controls and attributes. The SWU also provides watchpoint event status reporting, a global lock, and processor reset. A set of registers govern SWU operations. For more information on SWU functionality, see the SWU register descriptions.

**Table 36-1:** SWU Module Registers

| Name      | Description                  |
|-----------|------------------------------|
| SWU_GCTL  | Global Control Register      |
| SWU_GSTAT | Global Status Register       |
| SWU_CTLn  | Control Register n           |
| SWU_LAn   | Lower Address Register n     |
| SWU_UAn   | Upper Address Register n     |
| SWU_IDn   | ID Register n                |
| SWU_CNTn  | Count Register n             |
| SWU_TARGn | Target Register n            |
| SWU_HISTn | Bandwidth History Register n |
| SWU_CURn  | Current Register n           |

## ADSP-BF60x SWU Interrupt List

**Table 36-2:** ADSP-BF60x SWU Interrupt List

| Description | ID  | DMA Channel | Sensitivity |
|-------------|-----|-------------|-------------|
| SWU0 Event  | 133 |             | LEVEL       |

|             |    |             |

## SWU Definitions

### Watchpoint Mode

Mode in which transactions are recognized on an exact match. Actions can be configured to be taken after a specified number of matches have occurred.

### Bandwidth Mode

Mode in which transactions are recognized and counted inside sampling window.

## SWU Architectural Concepts

The information in this section provides basic module design concepts.

## SWU Flow Diagram

The following diagram shows the logical program flow of the SWU.

Figure 36-1: SWU Logical Flow

## SCB Interface

The SWU system crossbar interface block latches all transactions on the system crossbar read and write address channels when the SWU\_GCTL register enable bit is set.

## SWU Block Diagram

The following figure shows the SWU block diagram.

**Figure 36-2:** System Watchpoint Unit Top Level Block Diagram

## SWU Event Control

The SWU can generate the following events when a match occurs and when the event is enabled by configuring the proper bits in the control register.

1. Trace Message
2. Trigger
3. Interrupt
4. Debug

## SWU Interrupts

All interrupts and events from each match block are merged into common outputs.

## SWU Status and Errors

The status and errors are reported in the SWU\_ GSTAT register. The only error that the SWU records is an address error when a write or read attempt is made to the SWU's MMR address space and the register does not exist.

The SWU\_ GSTAT also holds the bits that indicate whether a particular match group sampled transactions that were below a minimum target or above a maximum target in bandwidth mode. There are separate status bits in SWU\_ GSTAT for each match group to indicate whether or not a watchpoint match occurred.

Finally, SWU\_GSTAT also hold status bits to indicate whether or not an interrupt was triggered due to a match event from one of the match groups.

## **SWU Operating Modes**

There are two operating modes supported by the SWU: bandwidth mode and watchpoint mode.

### **Bandwidth Mode**

In bandwidth mode, transactions which match the properties specified in the SWU\_CTLy register are counted during a sampling window determined by the respective SWU\_CNTy register. At the end of the sampling window, results are stored in the SWU\_HISTy register. If the sampled bandwidth falls outside a programmed range, then the programmed action is taken.

### **Watchpoint Mode**

In watchpoint mode, if the CNTEN bit is set, the SWUx\_CURy register is decremented for each match, until it equals zero, at which point any programmed actions are taken. The SWUx\_CURy register is then reloaded from the SWUx\_CNTy register (if CNT\_RPTEN is set), and the cycle repeats. If the CNTEN bit is not set, any programmed actions are taken on every match.

## **SWU Programming Model**

The SWU is used by programming the appropriate registers. Each control register is used to configure various aspects such as the direction of monitoring (reads or writes), whether Bandwidth Mode or Watchpoint Mode is used, setting up which events are triggered when a condition is met while monitoring using the SWU, and other parameters. Supplemental registers such as the lower and upper address boundaries are also configured before enabling.

Once the SWU has been enabled and monitoring conditions are met, events are generated if the SWU was configured to do so.

The global status register can be read to observe the current status of the units.

## **SWU Programming Concepts**

The information for this section is TBD.

## SWU Mode Configuration

The following sections show the steps for configuring the SWU into Bandwidth Mode and Watchpoint Mode.

### Configuring the SWU for Bandwidth Mode

In Bandwidth mode, transactions which match are counted during a sampling window. At the end of the sampling window, results are stored and an action can be taken if the sampled bandwidth goes above and/or falls below a programmed range.

1. Set the SWU\_CTLn.DIR bit depending on whether the SWU should test the match on writes or reads.
2. Set the SWU\_CTLn.ACMPM bits depending on whether address comparisons are made, exact match, matches inside a range or matches outside a range.
3. Optionally, set the SWU\_CTLn.IDCMPEN if ID comparison is desired.
4. Set the SWU\_CTLn.BLENINC bit to increment by burst length or clear it to increment by 1.
5. Set the MAXACT and MINACT bits in the SWU\_CTLn register to enable actions taken when the bandwidth goes above the maximum, or falls below the minimum, respectively.
6. Set the SWU\_CTLn.BWEN=1 to enable Bandwidth mode.
7. Program the lower address register, SWU\_LAn, and upper address register, SWU\_HAn, to define the memory range for comparison.
8. If ID comparison is enabled, program the ID register, SWU\_IDn.
9. Program the count register, SWU\_CNTn, with the number of clock cycles for which the SWU will be counting the number of matches.
10. If the SWU is set to take action when the bandwidth measurement underflows or overflows, the min and max values should be programmed into the SWU\_TARGn register.
11. Enable the SWU

#### *RESULT:*

The SWU counts the number of matches in a pre-defined amount of clock cycles programmed by the user. Lower and upper limits can optionally be defined. If the matches fall outside the limits, an action can be taken.

## Configuring the SWU for Watchpoint Mode

In watchpoint mode, the SWU can trigger a programmed action after every match or after a number of matches. This sequence can be automatically reset.

1. Set the `SWU_CTLn.DIR` bit to test the match on writes or reads.
2. Set the `SWU_CTLn.ACMPM` bits for address comparisons, exact match, matches inside a range or matches outside a range are desired.
3. Optionally set the `SWU_CTLn.IDCMPEN` if ID comparison is desired.
4. Set the `SWU_CTLn.CNTEN` bit to enable the events to be triggered when the count decrements to zero.
5. Optionally set the `SWU_CTLn.CNTRPTEN` bit to automatically reload the counter after it has decremented to zero to start another match sequence.
6. Set the `SWU_CTLn.BWEN = 0` to configure watchpoint mode.
7. Program the lower address register, `SWU_LAn`, and upper address register, `SWU_HAn`, to define the memory range for comparison.
8. If ID comparison is enabled, program the ID register, `SWU_IDn`.
9. Program the count register, `SWU_CNTn`, to determine how many matches occur before the watchpoint group takes action.
10. Enable the SWU.

### RESULT:

The SWU detects and counts down the number of match occurrences. When the counter expires, an action is taken.

## SWU Register Descriptions

System Watchpoint Unit (SWU) contains the following registers.

**Table 36-5:** SWU Module Registers

| Name      | Description             |
|-----------|-------------------------|
| SWU_GCTL  | Global Control Register |
| SWU_GSTAT | Global Status Register  |
| SWU_CTLn  | Control Register n      |

Table 36-5: SWU Module Registers (Continued)

| Name      | Description                  |
|-----------|------------------------------|
| SWU_LAn   | Lower Address Register n     |
| SWU_UAn   | Upper Address Register n     |
| SWU_IDn   | ID Register n                |
| SWU_CNTn  | Count Register n             |
| SWU_TARGn | Target Register n            |
| SWU_HISTn | Bandwidth History Register n |
| SWU_CURn  | Current Register n           |

Global Control Register

The SWU global control register (SWU\_GCTL) provides SWU reset and enable.

SWU\_GCTL: Global Control Register - R/W

Reset = 0x0000 0000

Figure 36-3: SWU\_GCTL Register Diagram

## Control Register n

The SWU control registers (SWU\_CTLn) contain watchpoint attribute controls for all four watchpoint groups. These controls include enabling watchpoints, selecting the transaction direction for match, selecting address comparison mode, enabling ID comparison, enabling security comparison, enabling locked comparison, enabling cycle count, enabling count repeat, enabling debug events, enabling interrupts, enabling triggers, enabling trace messages, enabling bandwidth mode, selecting the burst length increment, and enabling bandwidth underflow and overflow detection.

SWU\_CTLn: Control Register n - R/W

Reset = 0x0000 0000

|         |          | 1      Take Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 17      | BLENINC  | Increment Bandwidth Count by Burst Length.<br>Each SWU_CTLn.BLENINC bit controls how a watchpoint group's bandwidth count is incremented in the SWU_CURn register's SWU_CURn.CURBW field. If the SWU_CTLn.BLENINC bit is cleared (= 0), the SWU increments the bandwidth count by 1 for each matching transaction. If the SWU_CTLn.BLENINC bit is set (=1), the SWU increments the bandwidth count by the burst length of the transaction for each matching transaction. This feature is only valid for bandwidth mode (SWU_CTLn.BWEN bit == 1).<br>Note that if the address range match is enabled (SWU_CTLn.ACMPM bits) and if any address of a burst falls within the address range, the SWU_CURn.CURBW field is incremented by the burst length even if some of the burst address fall outside of the range.<br>Also, note that the burst size of the transaction is not included in the increment, only the burst length of the transaction. This increment operation provides an approximate (not exact) number of bus cycles consumed during the bandwidth. |
|         |          | 0      Increment by 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|         |          | 1      Burst Length Increment for Bandwidth Count                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 36-8:** SWU\_CTLn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | BWEN     | Bandwidth Mode Enable.<br>Each SWU_CTLn.BWEN bit controls whether a watchpoint group operates in watchpoint mode or bandwidth mode. In watchpoint mode, the SWU_CTLn.CNTEN and (optionally) SWU_CTLn.CNTRPTEN registers control usage of the cycle count for watchpoint group operations. In bandwidth mode, the SWU_CTLn.BLENINC, SWU_TARGn, and SWU_HISTn registers control usage of watchpoint matches for watchpoint group operations. |
|         |          | 0 Watchpoint Mode                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 11:10   | RESERVED | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 9       | CNTRPTEN | Count Repeat Enable.<br>Each SWU_CTLn.CNTRPTEN bit controls whether the watchpoint group's cycle count is reloaded and repeated after cycle countdown. If the SWU_CTLn register's SWU_CTLn.CNTRPTEN bit is set, the SWU_CURn register's SWU_CURn.CURCNT field is reloaded from SWU_CNTn register's SWU_CNTn.COUNT field, and the countdown starts again. If SWU_CTLn.CNTRPTEN bit is cleared, the expired count remains zero, and no further events are signalled. (See the SWU_CTLn.CNTEN bit description for information regarding the countdown setup.) |
|         |          | 0                      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         |          | 1                      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 8       | CNTEN    | Count Enable.<br>Each SWU_CTLn.CNTEN bit controls whether the cycle count in the watchpoint group's SWU_CNTn register is decremented each cycle until it reaches zero. This feature is only valid in watchpoint mode (SWU_CTLn.BWEN bit == 0). When the count reaches zero, any enabled watchpoint events are triggered. (See the SWU_CTLn.CNTRPTEN bit description for optional actions at that may occur at the end of the countdown.)                                                                                                                   |
|         |          | 0                      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         |          | 1                      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                                         |

## Lower Address Register n

The SWU lower address registers (SWU\_LAn) contain each watchpoint group's lower address for address match comparison. In exact match on SWU\_LAn address mode (SWU\_CTLn.ACMPM bits = 01), the watchpoint group uses only this address for match comparison.

**SWU\_LAn: Lower Address Register n - R/W**

Reset = 0x0000 0000

**Figure 36-6:** SWU\_LAn Register Diagram

Table 36-9: SWU\_LAn Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | ADDR     | Lower Address.          |

Upper Address Register n

The SWU upper address registers (SWU\_UAn) contain each watchpoint group's upper address for address match comparison. In exact match on SWU\_LAn address mode (SWU\_CTLn.ACMPM bits =01), the SWU\_UAn is not used for match comparison.

SWU\_UAn: Upper Address Register n - R/W

Reset = 0x0000 0000

Figure 36-7: SWU\_UAn Register Diagram

Table 36-10: SWU\_UAn Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | ADDR     | Upper Address.          |

ID Register n

The SWU ID registers (SWU\_IDn) contain a 16-bit ID field (SWU\_IDn.ID) and a 16-bit ID mask field (SWU\_IDn.IDMASK) that watchpoint groups use for ID comparison. The ID on the bus is AND'ed with the SWU\_IDn.IDMASK field, then the watchpoint group compares the result against the SWU\_IDn.ID field.

**SWU\_IDn: ID Register n - R/W**

Reset = 0x0000 0000

**Figure 36-8:** SWU\_IDn Register Diagram

**Table 36-11:** SWU\_IDn Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 31:16   | IDMASK   | Identity Mask (for Or with ID). |
| 15:0    | ID       | Identity.                       |

## Count Register n

The SWU count registers (SWU\_CNTn) contain a 16-bit count field (SWU\_CNTn.COUNT) whose usage differs depending on the mode of the watchpoint group. In bandwidth mode, the SWU\_CNTn.COUNT field value defines the number of clock cycles in a bandwidth period. In watchpoint mode, when the cycle count is enabled, the SWU\_CNTn.COUNT field value determines how many matches occur before the watchpoint group takes action.

**SWU\_CNTn: Count Register n - R/W**

Reset = 0x0000 0000

**Figure 36-9:** SWU\_CNTn Register Diagram

**Table 36-12:** SWU\_CNTn Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | RESERVED | Reserved.               |
| 15:0    | COUNT    | Count.                  |

Target Register n

The SWU target registers (SWU\_TARGn) contain a minimum value field (SWU\_TARGn.BWMIN) and maximum value field (SWU\_TARGn.BWMAX) of bandwidth targets used by watchpoint groups in bandwidth mode. When the bandwidth period expires, if the current bandwidth value (SWU\_CURn register, SWU\_CURn.CURBW bits) is below the minimum target or above the maximum target, the watchpoint group takes action as enabled by the SWU\_CTLn register's SWU\_CTLn.MINACT or SWU\_CTLn.MAXACT bits.

In bandwidth mode, note that the watchpoint group increments its count of either data bus transactions or address bus transactions (bursts) as selected by the SWU\_CTLn.BLENINC bit. Keep this mode selection in mind when programming the bandwidth target values.

SWU\_TARGn: Target Register n - R/W

Reset = 0x0000 0000

**Figure 36-10:** SWU\_TARGn Register Diagram

**Table 36-13:** SWU\_TARGn Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 31:16   | BWMAX    | Maximum Bandwidth Target. |
| 15:0    | BWMIN    | Minimum Bandwidth Target. |

## Bandwidth History Register n

The SWU bandwidth history registers (SWU\_HISTn) contain data copied from a watchpoint group's current bandwidth value (SWU\_CURn register, SWU\_CURn.CURBW bits) at the end of the last two watchpoint periods. At the end of each watchpoint period, the SWU copies the previous bandwidth value from the SWU\_HISTn.BWHIST0 field to the SWU\_HISTn.BWHIST1 field and copies the new bandwidth value from the SWU\_CURn.CURBW field to the SWU\_HISTn.BWHIST0 field.

**SWU\_HISTn: Bandwidth History Register n - R/W**

Reset = 0x0000 0000

**Figure 36-11:** SWU\_HISTn Register Diagram

**Table 36-14:** SWU\_HISTn Register Fields

| Bit No. | Bit Name | Description/Enumeration            |
|---------|----------|------------------------------------|
| 31:16   | BWHIST1  | Bandwidth from Window Before Last. |
| 15:0    | BWHIST0  | Bandwidth from Last Window.        |

## Current Register n

The SWU current register (SWU\_CURn) operation varies depending whether the watchpoint group is in bandwidth mode or watchpoint mode. In both modes, the watchpoint count begins when the SWU loads the register's SWU\_CURn.CURCNT field from the SWU\_CNTn register's SWU\_CNTn.COUNT field when the watchpoint count is enabled (SWU\_CTLn register, SWU\_CTLn.CNTEN bit =1).

In bandwidth mode, the current count field (SWU\_CURn.CURCNT) contains the cycle count remaining within the current watchpoint period. The SWU decrements this value every cycle until the count reaches zero. At that point, the SWU reloads the SWU\_CURn.CURCNT field from SWU\_CNTn register's SWU\_CNTn.COUNT field. In bandwidth mode, the current bandwidth field (SWU\_CURn.CURBW) contains the count of watchpoint matches (bandwidth) accumulated in the current watchpoint period.

In watchpoint mode, the current count field (SWU\_CURn.CURCNT) contains the watchpoint match count remaining within the current watchpoint period. The SWU decrements this value with every watchpoint match until the count reaches zero. At that point, the SWU reloads the SWU\_CURn.CURCNT field from

SWU\_CNTn register's SWU\_CNTn.COUNT field if the SWU\_CTLn register's SWU\_CTLn.CNTRPTEN bit is set (=1).  
In watchpoint mode, the current bandwidth field (SWU\_CURn.CURBW) is undefined.

SWU\_CURn: Current Register n - R/W

Reset = 0x0000 0000

Figure 36-12: SWU\_CURn Register Diagram

Table 36-15: SWU\_CURn Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | CURBW    | Current Bandwidth.      |
| 15:0    | CURCNT   | Current Count.          |

 Current Row Count (2D only), DMA (DMA\_YCNT\_CUR), 13-67

## D

Data Compare Register, CRC (CRC\_COMP), 12-34  
 Data Control Register, RSI (RSI\_DATA\_CTL), 24-52  
 Data Count Capture Register, CRC (CRC\_DCNTCAP), 12-42  
 Data Count Register, RSI (RSI\_DATA\_CNT), 24-53  
 Data FIFO Register, CRC (CRC\_DFIFO), 12-36  
 Data FIFO Register, RSI (RSI\_FIFO), 24-64  
 Data Interrupt Latch Register, TIMER (TIMER\_DATA\_ILAT), 15-36  
 Data Interrupt Mask Register, TIMER (TIMER\_DATA\_IMSK), 15-34  
 Data Length Register, RSI (RSI\_DATA\_LEN), 24-52  
 Data Timer Register, RSI (RSI\_DATA\_TMR), 24-51  
 Data Word Count Register, CRC (CRC\_DCNT), 12-33  
 Data Word Count Reload Register, CRC (CRC\_DCNTRLD), 12-34  
 Dead Time Register, PWM (PWM\_DT), 18-67  
 Debounce Register, CNT (CNT\_DEBNCE), 17-23  
 Debug Register, CAN (CAN\_DBG), 21-49  
 Debug Register, EMAC (EMAC\_DBG), 23-123  
 Delay Register, SPI (SPI\_DLY), 25-38  
 Device Control Register, USB (USB\_DEV\_CTL), 22-114  
 Divisor Register, CGU (CGU\_DIV), 3-17  
 DLL Control Register, DMC (DMC\_DLLCTL), 11-43  
 DMA Bus Mode Register, EMAC (EMAC\_DMA\_BUSMODE), 23-223  
 DMA Channel n Address Register, USB (USB\_DMAAn\_ADDR), 22-179  
 DMA Channel n Control Register, USB

(USB\_DMAAn\_CTL), 22-176  
 DMA Channel n Count Register, USB (USB\_DMAAn\_CNT), 22-179  
 DMA Controller Error interrupt, 7-9  
 DMA Interrupt Enable Register, EMAC (EMAC\_DMA\_IEN), 23-240  
 DMA Interrupt Register, USB (USB\_DMA\_IRQ), 22-173  
 DMA Missed Frame Register, EMAC (EMAC\_DMA\_MISS\_FRM), 23-243  
 DMA Operation Mode Register, EMAC (EMAC\_DMA\_OPMODE), 23-235  
 DMA Read Data Register, SDU (SDU\_DMARD), 35-24  
 DMA Rx Buffer Current Register, EMAC (EMAC\_DMA\_RXBUF\_CUR), 23-249  
 DMA Rx Descriptor Current Register, EMAC (EMAC\_DMA\_RXDSC\_CUR), 23-248  
 DMA Rx Descriptor List Address Register, EMAC (EMAC\_DMA\_RXDSC\_ADDR), 23-227  
 DMA Rx Interrupt Watch Dog Register, EMAC (EMAC\_DMA\_RXIWDOG), 23-244  
 DMA Rx Poll Demand register, EMAC (EMAC\_DMA\_RXPOLL), 23-226  
 DMA SCB Bus Mode Register, EMAC (EMAC\_DMA\_BMMODE), 23-245  
 DMA SCB Status Register, EMAC (EMAC\_DMA\_BMSTAT), 23-246  
 DMA Status Register, EMAC (EMAC\_DMA\_STAT), 23-229  
 DMA Tx Buffer Current Register, EMAC (EMAC\_DMA\_TXBUF\_CUR), 23-248  
 DMA Tx Descriptor Current Register, EMAC (EMAC\_DMA\_TXDSC\_CUR), 23-247  
 DMA Tx Descriptor List Address Register, EMAC (EMAC\_DMA\_TXDSC\_ADDR), 23-228  
 DMA Tx Poll Demand Register, EMAC (EMAC\_DMA\_TXPOLL), 23-226  
 DMA Write Data Register, SDU (SDU\_DMAWD), 35-24  
 DMA\_ADDR\_CUR (Current Address, DMA), 13-61  
 DMA\_ADDRSTART (Start Address of Current Buffer, DMA), 13-47  
 DMA\_BWLCNT (Bandwidth Limit Count, DMA), 13-68

- DMA\_BWLCNT\_CUR (Bandwidth Limit Count Current, DMA), 13-69  
 DMA\_BWMCNT (Bandwidth Monitor Count, DMA), 13-69  
 DMA\_BWMCNT\_CUR (Bandwidth Monitor Count Current, DMA), 13-70  
 DMA\_CFG (Configuration Register, DMA), 13-48  
 DMA\_DSCPTR\_CUR (Current Descriptor Pointer, DMA), 13-60  
 DMA\_DSCPTR\_NXT (Pointer to Next Initial Descriptor, DMA), 13-47  
 DMA\_DSCPTR\_PRV (Previous Initial Descriptor Pointer, DMA), 13-61  
 DMA\_STAT (Status Register, DMA), 13-62  
 DMA\_XCNT (Inner Loop Count Start Value, DMA), 13-57  
 DMA\_XCNT\_CUR (Current Count(1D) or intra-row XCNT (2D), DMA), 13-67  
 DMA\_XMOD (Inner Loop Address Increment, DMA), 13-58  
 DMA\_YCNT (Outer Loop Count Start Value (2D only), DMA), 13-58  
 DMA\_YCNT\_CUR (Current Row Count (2D only), DMA), 13-67  
 DMA\_YMOD (Outer Loop Address Increment (2D only), DMA), 13-59  
 DMC\_CFG (Configuration Register, DMC), 11-28  
 DMC\_CTL (Control Register, DMC), 11-16  
 DMC\_DLLCTL (DLL Control Register, DMC), 11-43  
 DMC\_EFFECTL (Efficiency Control Register, DMC), 11-22  
 DMC\_EMR1 (Shadow EMR1 Register, DMC), 11-38  
 DMC\_EMR2 (Shadow EMR2 Register, DMC), 11-40  
 DMC\_EMR3 (Shadow EMR3 Register, DMC), 11-42  
 DMC\_MR (Shadow MR Register, DMC), 11-35  
 DMC\_MSK (Mask (Mode Register Shadow) Register, DMC), 11-33  
 DMC\_PADCTL (PAD Control Register, DMC), 11-47  
 DMC\_PHY\_CTL1 (PHY Control 1 Register, DMC), 11-44  
 DMC\_PHY\_CTL3 (PHY Control 3 Register, DMC), 11-45  
 DMC\_PRIO (Priority ID Register, DMC), 11-26  
 DMC\_PRIOMSK (Priority ID Mask Register, DMC), 11-27  
 DMC\_STAT (Status Register, DMC), 11-19  
 DMC\_TR0 (Timing 0 Register, DMC), 11-29  
 DMC\_TR1 (Timing 1 Register, DMC), 11-31  
 DMC\_TR2 (Timing 2 Register, DMC), 11-32  
 DPM0 Event interrupt, 5-2, 7-9  
 DPM\_CCBF\_DIS (Core Clock Buffer Disable Register, DPM), 5-18  
 DPM\_CCBF\_EN (Core Clock Buffer Enable Register, DPM), 5-19  
 DPM\_CCBF\_STAT (Core Clock Buffer Status Register, DPM), 5-20  
 DPM\_CCBF\_STAT\_STKY (Core Clock Buffer Status Sticky Register, DPM), 5-20  
 DPM\_CTL (Control Register, DPM), 5-13  
 DPM\_HIB\_DIS (Hibernate Disable Register, DPM), 5-25  
 DPM\_PGCNTR (Power Good Counter Register, DPM), 5-26  
 DPM\_RESTOREn (Restore n Register, DPM), 5-28  
 DPM\_SCBF\_DIS (System Clock Buffer Disable Register, DPM), 5-21  
 DPM\_STAT (Status Register, DPM), 5-15  
 DPM\_WAKE\_EN (Wakeup Enable Register, DPM), 5-22  
 DPM\_WAKE\_POL (Wakeup Polarity Register, DPM), 5-23  
 DPM\_WAKE\_STAT (Wakeup Status Register, DPM), 5-24

 Fault System Reset Delay Current Register, SEC (SEC\_FSRDLY\_CUR), 7-38  
 Fault System Reset Delay Register, SEC (SEC\_FSRDLY), 7-37  
 FIFO Byte (8-Bit) Register, USB (USB\_FIFOBn), 22-112  
 FIFO Control Register, TWI (TWI\_FIFOCTL), 20-37  
 FIFO Counter Register, RSI (RSI\_FIFO\_CNT), 24-61  
 FIFO Half-Word (16-Bit) Register, USB (USB\_FIFOHn), 22-113  
 FIFO Status Register, TWI (TWI\_FIFOSTAT), 20-38  
 FIFO Word (32-Bit) Register, USB (USB\_FIFOn), 22-114  
 Fill Value Register, CRC (CRC\_FILLVAL), 12-35  
 FLow Control Register, EMAC (EMAC\_FLOWCTL), 23-120  
 Frame Number Register, USB (USB\_FRAME), 22-109  
 Frame Sync 1 Delay Value, EPPI (EPPI\_FS1\_DLY), 31-94  
 Frame Sync 2 Delay Value, EPPI (EPPI\_FS2\_DLY),

31-95  
 FS1 Period Register / EPPI Active Samples Per Line Register, EPPI (EPPI\_FS1\_PASPL), 31-88  
 FS1 Width Register / EPPI Horizontal Blanking Samples Per Line Register, EPPI (EPPI\_FS1\_WLHB), 31-87  
 FS2 Period Register / EPPI Active Lines Per Field Register, EPPI (EPPI\_FS2\_PALPF), 31-90  
 FS2 Width Register / EPPI Lines Of Vertical Blanking Register, EPPI (EPPI\_FS2\_WLVB), 31-89  
 Full-Speed EOF 1 Register, USB (USB\_FS\_EOF1), 22-125  
 Function Address Register, USB (USB\_FADDR), 22-89

## G

Global CAN Interrupt Flag Register, CAN (CAN\_GIF), 21-61  
 Global CAN Interrupt Mask Register, CAN (CAN\_GIM), 21-58  
 Global CAN Interrupt Status Register, CAN (CAN\_GIS), 21-55  
 Global Control Register, SEC (SEC\_GCTL), 7-40  
 Global Control Register, SWU (SWU\_GCTL), 36-10  
 Global Control Register, TRU (TRU\_GCTL), 8-18  
 Global End Register, SEC (SEC\_END), 7-43  
 Global Raise Register, SEC (SEC\_RAISE), 7-43  
 Global Status Register, SEC (SEC\_GSTAT), 7-41  
 Global Status Register, SWU (SWU\_GSTAT), 36-12  
 Grant Control Register, SMC (SMC\_GCTL), 9-24  
 Grant Status Register, SMC (SMC\_GSTAT), 9-25  
 Group Halt Register, SDU (SDU\_GHLT), 35-28  
 GU Conversion Component Register, PIXC (PIXC\_CONGU), 32-47

## H

Half SPORT 'A' Control 2 Register, SPORT (SPORT\_CTL2\_A), 26-71  
 Half SPORT 'A' Control Register, SPORT (SPORT\_CTL\_A), 26-52  
 Half SPORT 'A' Divisor Register, SPORT (SPORT\_DIV\_A), 26-62  
 Half SPORT 'A' Error Register, SPORT (SPORT\_ERR\_A), 26-68

Half SPORT 'A' Multi-channel 0-31 Select Register, SPORT (SPORT\_CS0\_A), 26-65

Half SPORT 'A' Multi-channel 32-63 Select Register, SPORT (SPORT\_CS1\_A), 26-66

Half SPORT 'A' Multi-channel 64-95 Select Register, SPORT (SPORT\_CS2\_A), 26-67

Half SPORT 'A' Multi-channel 96-127 Select Register, SPORT (SPORT\_CS3\_A), 26-67

Half SPORT 'A' Multi-channel Control Register, SPORT (SPORT\_MCTL\_A), 26-63

Half SPORT 'A' Multi-channel Status Register, SPORT (SPORT\_MSTAT\_A), 26-71

Half SPORT 'A' Rx Buffer (Primary) Register, SPORT (SPORT\_RXPRI\_A), 26-74

Half SPORT 'A' Rx Buffer (Secondary) Register, SPORT (SPORT\_RXSEC\_A), 26-76

Half SPORT 'A' Tx Buffer (Primary) Register, SPORT (SPORT\_TXPRI\_A), 26-73

Half SPORT 'A' Tx Buffer (Secondary) Register, SPORT (SPORT\_TXSEC\_A), 26-75

Half SPORT 'B' Control 2 Register, SPORT (SPORT\_CTL2\_B), 26-96

Half SPORT 'B' Control Register, SPORT (SPORT\_CTL\_B), 26-77

Half SPORT 'B' Divisor Register, SPORT (SPORT\_DIV\_B), 26-87

Half SPORT 'B' Error Register, SPORT (SPORT\_ERR\_B), 26-93

Half SPORT 'B' Multi-channel 0-31 Select Register, SPORT (SPORT\_CS0\_B), 26-90

Half SPORT 'B' Multi-channel 32-63 Select Register, SPORT (SPORT\_CS1\_B), 26-91

Half SPORT 'B' Multichannel 64-95 Select Register, SPORT (SPORT\_CS2\_B), 26-92

Half SPORT 'B' Multichannel 96-127 Select Register, SPORT (SPORT\_CS3\_B), 26-92

Half SPORT 'B' Multi-channel Control Register, SPORT (SPORT\_MCTL\_B), 26-88

Half SPORT 'B' Multi-channel Status Register, SPORT (SPORT\_MSTAT\_B), 26-96

Half SPORT 'B' Rx Buffer (Primary) Register, SPORT (SPORT\_RXPRI\_B), 26-99

Half SPORT 'B' Rx Buffer (Secondary) Register, SPORT (SPORT\_RXSEC\_B), 26-101

Half SPORT 'B' Tx Buffer (Primary) Register, SPORT

(SPORT\_TXPRI\_B), 26-98

Half SPORT 'B' Tx Buffer (Secondary) Register, SPORT (SPORT\_TXSEC\_B), 26-100

Hash Table High Register, EMAC (EMAC\_HASHTBL\_HI), 23-116

Hash Table Low Register, EMAC (EMAC\_HASHTBL\_LO), 23-116

Hibernate Disable Register, DPM (DPM\_HIB\_DIS), 5-25

High Speed Timeout Register, USB (USB\_CT\_HSBT), 22-182

High-Speed EOF 1 Register, USB (USB\_HS\_EOF1), 22-125

Horizontal Delay Count Register, EPPI (EPPI\_HDL\_Y), 31-72

Horizontal Transfer Count Register, EPPI (EPPI\_HCNT), 31-72

Host High Speed Return to Normal Register, USB (USB\_CT\_HHSRTN), 22-181

## I

ID Code Register, SDU (SDU\_IDCODE), 35-13

ID Register n, SWU (SWU\_IDn), 36-23

IIMn Configuration, PVP (PVP\_IIMn\_CFG), 30-146

IIMn Control, PVP (PVP\_IIMn\_CTL), 30-148

IIMn Scaling Values, PVP (PVP\_IIMn\_SCALE), 30-149

IIMn Signed Overflow Status, PVP (PVP\_IIMn\_SOVF\_STAT), 30-150

IIMn Unsigned Overflow Status, PVP (PVP\_IIMn\_UOVF\_STAT), 30-151

Index Register, USB (USB\_INDEX), 22-110

Inner Loop Address Increment, DMA (DMA\_XMOD), 13-58

Inner Loop Count Start Value, DMA (DMA\_XCNT), 13-57

Interrupt 0 Mask Register, RSI (RSI\_XFR\_IMSK0), 24-57

Interrupt 1 Mask Register, RSI (RSI\_XFR\_IMSK1), 24-59

Interrupt Enable Clear Register, CRC (CRC\_INEN\_CLR), 12-38

Interrupt Enable Register, CRC (CRC\_INEN), 12-36

Interrupt Enable Set Register, CRC (CRC\_INEN\_SET), 12-37

Interrupt Latch Register, PWM (PWM\_ILAT), 18-64  
 Interrupt Latch Status n, PVP (PVP\_ILAT), 30-125  
 Interrupt Mask Clear Register, SPI (SPI\_IMSK\_CLR), 25-49  
 Interrupt Mask Clear Register, UART (UART\_IMSK\_CLR), 19-47  
 Interrupt Mask n, PVP (PVP\_IMSKn), 30-113  
 Interrupt Mask Register, CNT (CNT\_IMSK), 17-18  
 Interrupt Mask Register, EMAC (EMAC\_IMSK), 23-127  
 Interrupt Mask Register, EPPI (EPPI\_IMSK), 31-91  
 Interrupt Mask Register, PWM (PWM\_IMSK), 18-62  
 Interrupt Mask Register, SPI (SPI\_IMSK), 25-47  
 Interrupt Mask Register, TWI (TWI\_IMSK), 20-35  
 Interrupt Mask Register, UART (UART\_IMSK), 19-41  
 Interrupt Mask Set Register, SPI (SPI\_IMSK\_SET), 25-50  
 Interrupt Mask Set Register, UART (UART\_IMSK\_SET), 19-45  
 Interrupt Pending Register, CAN (CAN\_INT), 21-66  
 Interrupt Request n, PVP (PVP\_IREQn), 30-130  
 Interrupt Status Register, EMAC (EMAC\_ISTAT), 23-126  
 Interrupt Status Register, PIXC (PIXC\_IRQSTAT), 32-45  
 Interrupt Status Register, TWI (TWI\_ISTAT), 20-31  
 IPF0 (Camera Pipe) Configuration, PVP (PVP\_IPF0\_CFG), 30-164  
 IPF0 (Camera Pipe) Horizontal Position, PVP (PVP\_IPF0\_HPOS), 30-172  
 IPF0 (Camera Pipe) Vertical Position, PVP (PVP\_IPF0\_VPOS), 30-173  
 IPF1 (Memory Pipe) Configuration, PVP (PVP\_IPF1\_CFG), 30-174  
 IPFn (Camera/Memory Pipe) Control, PVP (PVP\_IPFn\_CTL), 30-166  
 IPFn (Camera/Memory Pipe) Frame Count, PVP (PVP\_IPFn\_FCNT), 30-170  
 IPFn (Camera/Memory Pipe) Horizontal Count, PVP (PVP\_IPFn\_HCNT), 30-171  
 IPFn (Camera/Memory Pipe) Pipe Control, PVP (PVP\_IPFn\_PIPECTL), 30-165  
 IPFn (Camera/Memory Pipe) TAG Status, PVP (PVP\_IPFn\_TAG\_STAT), 30-173

IPFn (Camera/Memory Pipe) TAG Value, PVP (PVP\_IPFn\_TAG), 30-170  
 IPFn (Camera/Memory Pipe) Vertical Count, PVP (PVP\_IPFn\_VCNT), 30-171

## L

L2CTL0 ECC Error interrupt, 7-3, 10-2

 UART0 Status interrupt, 7-7, 19-4  
 UART0 Transmit DMA (Masters), 8-4, 19-4  
 UART0 Transmit DMA (Slaves), 8-8, 19-4  
 UART0 Transmit DMA interrupt, 7-6, 19-4  
 UART1 Receive DMA (Masters), 8-4, 19-4  
 UART1 Receive DMA (Slaves), 8-8, 19-5  
 UART1 Receive DMA interrupt, 7-7, 19-4  
 UART1 Status interrupt, 7-7, 19-4  
 UART1 Transmit DMA (Masters), 8-4, 19-4  
 UART1 Transmit DMA (Slaves), 8-8, 19-4  
 UART1 Transmit DMA interrupt, 7-7, 19-4  
 UART\_CLK (Clock Rate Register, UART), 19-40  
 UART\_CTL (Control Register, UART), 19-26  
 UART\_IMSK (Interrupt Mask Register, UART),  
 19-41

UART\_IMSK\_CLR (Interrupt Mask Clear Register,  
 UART), 19-47  
 UART\_IMSK\_SET (Interrupt Mask Set Register,  
 UART), 19-45  
 UART\_RBR (Receive Buffer Register, UART), 19-49  
 UART\_REVID (Revision ID Register, UART), 19-25  
 UART\_RSR (Receive Shift Register, UART), 19-52  
 UART\_RXCNT (Receive Counter Register, UART),  
 19-53  
 UART\_SCR (Scratch Register, UART), 19-39  
 UART\_STAT (Status Register, UART), 19-34  
 UART\_TAIP (Transmit Address/Insert Pulse Register,  
 UART), 19-51  
 UART\_THR (Transmit Hold Register, UART), 19-50  
 UART\_TSR (Transmit Shift Register, UART), 19-51  
 UART\_TXCNT (Transmit Counter Register, UART),  
 19-53  
 UDS Configuration, PVP (PVP\_UDS\_CFG), 30-160  
 UDS Control, PVP (PVP\_UDS\_CTL), 30-161  
 UDS HAVG, PVP (PVP\_UDS\_HAVG), 30-163  
 UDS Output HCNT, PVP (PVP\_UDS\_OHCNT),  
 30-162  
 UDS Output VCNT, PVP (PVP\_UDS\_OVCNT),  
 30-162  
 UDS VAVG, PVP (PVP\_UDS\_VAVG), 30-164  
 Universal Counter Configuration Mode Register, CAN  
 (CAN\_UCCNF), 21-73  
 Universal Counter Register, CAN (CAN\_UCCNT),  
 21-72  
 Universal Counter Reload/Capture Register, CAN  
 (CAN\_UCRC), 21-72  
 Upper Address Register n, SWU (SWU\_UAn), 36-22  
 USB0 DMA Status/Transfer Complete (Masters), 8-6,  
 22-9  
 USB0 DMA Status/Transfer Complete interrupt, 7-9,  
 22-9  
 USB0 Status/FIFO Data Ready interrupt, 7-9, 22-8  
 USB\_BAT\_CHG (Battery Charging Control Register,  
 USB), 22-193  
 USB\_CT\_HHSRTN (Host High Speed Return to Nor-  
 mal Register, USB), 22-181  
 USB\_CT\_HSBT (High Speed Timeout Register,  
 USB), 22-182  
 USB\_CT\_UCH (Chirp Timeout Register, USB),  
 22-181

- USB\_DEV\_CTL (Device Control Register, USB), 22-114
- USB\_DMA\_IRQ (DMA Interrupt Register, USB), 22-173
- USB\_DMAn\_ADDR (DMA Channel n Address Register, USB), 22-179
- USB\_DMAn\_CNT (DMA Channel n Count Register, USB), 22-179
- USB\_DMAn\_CTL (DMA Channel n Control Register, USB), 22-176
- USB\_EP0\_CFGDATAn (EP0 Configuration Information Register, USB), 22-171
- USB\_EP0\_CNTn (EP0 Number of Received Bytes Register, USB), 22-161
- USB\_EP0\_CSRn\_H (EP0 Configuration and Status (Host) Register, USB), 22-133
- USB\_EP0\_CSRn\_P (EP0 Configuration and Status (Peripheral) Register, USB), 22-137
- USB\_EP0\_NAKLIMITn (EP0 NAK Limit Register, USB), 22-165
- USB\_EP0\_TYPEn (EP0 Connection Type Register, USB), 22-165
- USB\_EPINFO (Endpoint Information Register, USB), 22-122
- USB\_EPn\_RXCNT (EPn Number of Bytes Received Register, USB), 22-161
- USB\_EPn\_RXCSR\_H (EPn Receive Configuration and Status (Host) Register, USB), 22-150
- USB\_EPn\_RXCSR\_P (EPn Receive Configuration and Status (Peripheral) Register, USB), 22-156
- USB\_EPn\_RXINTERVAL (EPn Receive Polling Interval Register, USB), 22-170
- USB\_EPn\_RXMAXP (EPn Receive Maximum Packet Length Register, USB), 22-149
- USB\_EPn\_RXTYPE (EPn Receive Type Register, USB), 22-167
- USB\_EPn\_TXCSR\_H (EPn Transmit Configuration and Status (Host) Register, USB), 22-140
- USB\_EPn\_TXCSR\_P (EPn Transmit Configuration and Status (Peripheral) Register, USB), 22-145
- USB\_EPn\_TXINTERVAL (EPn Transmit Polling Interval Register, USB), 22-166
- USB\_EPn\_TXMAXP (EPn Transmit Maximum Packet Length Register, USB), 22-132
- USB\_EPn\_TXTYPE (EPn Transmit Type Register, USB), 22-162
- USB\_FADDR (Function Address Register, USB), 22-89
- USB\_FIFOBn (FIFO Byte (8-Bit) Register, USB), 22-112
- USB\_FIFOHn (FIFO Half-Word (16-Bit) Register, USB), 22-113
- USB\_FIFOn (FIFO Word (32-Bit) Register, USB), 22-114
- USB\_FRAME (Frame Number Register, USB), 22-109
- USB\_FS\_EOF1 (Full-Speed EOF 1 Register, USB), 22-125
- USB\_HS\_EOF1 (High-Speed EOF 1 Register, USB), 22-125
- USB\_IEN (Common Interrupts Enable Register, USB), 22-107
- USB\_INDEX (Index Register, USB), 22-110
- USB\_INTRRX (Receive Interrupt Register, USB), 22-96
- USB\_INTRRXE (Receive Interrupt Enable Register, USB), 22-102
- USB\_INTRTX (Transmit Interrupt Register, USB), 22-93
- USB\_INTRTXE (Transmit Interrupt Enable Register, USB), 22-99
- USB\_IRQ (Common Interrupts Register, USB), 22-105
- USB\_LINKINFO (Link Information Register, USB), 22-123
- USB\_LPM\_ATTR (LPM Attribute Register, USB), 22-183
- USB\_LPM\_CTL (LPM Control Register, USB), 22-184
- USB\_LPM\_FADDR (LPM Function Address Register, USB), 22-191
- USB\_LPM\_IEN (LPM Interrupt Enable Register, USB), 22-187
- USB\_LPM\_IRQ (LPM Interrupt Status Register, USB), 22-188
- USB\_LS\_EOF1 (Low-Speed EOF 1 Register, USB), 22-126
- USB\_MPn\_RXFUNCADDR (MPn Receive Function Address Register, USB), 22-130
- USB\_MPn\_RXHUBADDR (MPn Receive Hub Ad-

dress Register, USB), 22-130  
 USB\_MPn\_RXHUBPORT (MPn Receive Hub Port Register, USB), 22-131  
 USB\_MPn\_TXFUNCADDR (MPn Transmit Function Address Register, USB), 22-128  
 USB\_MPn\_TXHUBADDR (MPn Transmit Hub Address Register, USB), 22-128  
 USB\_MPn\_TXHUBPORT (MPn Transmit Hub Port Register, USB), 22-129  
 USB\_PHY\_CTL (PHY Control Register, USB), 22-194  
 USB\_PLL\_OSC (PLL and Oscillator Control Register, USB), 22-195  
 USB\_POWER (Power and Device Control Register, USB), 22-89  
 USB\_RAMINFO (RAM Information Register, USB), 22-123  
 USB\_RQPKTCNTn (EPn Request Packet Count Register, USB), 22-180  
 USB\_RXFIFOADDR (Receive FIFO Address Register, USB), 22-121  
 USB\_RXFIFOSZ (Receive FIFO Size Register, USB), 22-119  
 USB\_SOFT\_RST (Software Reset Register, USB), 22-127  
 USB\_TESTMODE (Testmode Register, USB), 22-111  
 USB\_TXFIFOADDR (Transmit FIFO Address Register, USB), 22-121  
 USB\_TXFIFOSZ (Transmit FIFO Size Register, USB), 22-117  
 USB\_VBUS\_CTL (VBUS Control Register, USB), 22-192  
 USB\_VPLEN (VBUS Pulse Length Register, USB), 22-124

## V

VBUS Control Register, USB (USB\_VBUS\_CTL), 22-192  
 VBUS Pulse Length Register, USB (USB\_VPLEN), 22-124  
 Vertical Delay Count Register, EPPI (EPPI\_VDLY), 31-74  
 Vertical Transfer Count Register, EPPI (EPPI\_VCNT), 31-73  
 VID\_CONN (Video Subsystem Connect Register,

VID), 29-8  
 Video Subsystem Connect Register, VID (VID\_CONN), 29-8  
 VLAN Tag Register, EMAC (EMAC\_VLANTAG), 23-122

## W

Wakeup Enable Register, DPM (DPM\_WAKE\_EN), 5-22  
 Wakeup Polarity Register, DPM (DPM\_WAKE\_POL), 5-23  
 Wakeup Status Register, DPM (DPM\_WAKE\_STAT), 5-24  
 Watchdog Timer Status Register, WDOG (WDOG\_STAT), 16-6  
 WDOG0 Expiration interrupt, 7-3, 16-2  
 WDOG1 Expiration interrupt, 7-3, 16-2  
 WDOG\_CNT (Count Register, WDOG), 16-5  
 WDOG\_CTL (Control Register, WDOG), 16-4  
 WDOG\_STAT (Watchdog Timer Status Register, WDOG), 16-6  
 Write Priority Count Register, L2CTL (L2CTL\_WPCR), 10-24  
 Write Protect Register n, SPU (SPU\_WPn), 4-10
